

# Structural and mutational characterisation of *Shigella* Pathogenicity Factors

**Dissertation**  
zur Erlangung des Doktorgrades  
der Naturwissenschaften  
(Dr. rer. nat.)

dem Fachbereich Pharmazie  
der Philipps-Universität Marburg  
vorgelegt von

**Naomi Tidten**  
aus Bonn

Marburg/Lahn 2007

Die Untersuchungen zur vorliegenden Arbeit wurden auf Anregung von Herrn PD Dr. Klaus Reuter und Herrn Prof. Dr. Gerhard Klebe am Institut für Pharmazeutische Chemie des Fachbereichs Pharmazie der Philipps-Universität Marburg in der Zeit von Mai 2004 bis Dezember 2007 durchgeführt.

Vom Fachbereich Pharmazie der Philipps-Universität Marburg als Dissertation am 15.02.2008 angenommen.

Erstgutachter: Prof. Dr. Gerhard Klebe

Zweitgutachter: PD Dr. Klaus Reuter

Tag der mündlichen Prüfung: 15.02.2008

In Erinnerung an meinen Großvater

Es gibt mehr Leute, die kapitulieren, als solche, die scheitern.

## Table of contents

Table of contents.....	I
Figures and Tables .....	V
1 Introduction.....	1
1.1 Bacillary dysentery – Shigellosis .....	1
<i>Shigellae</i> classification.....	1
1.2 Pathogenesis by <i>Shigellae</i> .....	2
1.3 Molecular basis of the <i>Shigella</i> invasion mechanism.....	6
1.3.1 Pathogenicity factor IpaA, its chaperone Spa15 and the host cell protein Vinculin .....	7
1.3.2 Pathogenicity factor IpgD and its chaperone IpgE .....	9
1.3.3 Pathogenicity factor OspD1 .....	10
1.3.4 Pathogenicity factor IpgB2.....	11
1.3.5 Pathogenicity factor VirF .....	11
1.4 tRNA guanine transglycosylase, the gene product of <i>vacC</i> is a target for structure-based drug design.....	12
1.5 Aims of the project .....	14
1.5.1 Pathogenicity factors IpaA, IpgE, IpgB2 and OspD1 .....	14
1.5.2 Substrate selectivity and specificity study of tRNA guanine transglycosylases of the three domains of life, based on a <i>Zymomonas mobilis</i> TGT model system.....	14
1.6 References .....	16
2 Selected <i>Shigella</i> Pathogenicity Factors .....	21
2.1 Cloning and Expression of <i>ipaA</i> , <i>spa15</i> , <i>vinc_hd</i> , <i>ipgB2</i> , <i>ospD1</i> , <i>ipgE</i> .....	22
2.2 Purification of Pathogenicity Factors IpgB2, OspD1 and IpgE .....	26
2.2.1 IpgB2 .....	26
2.2.2 OspD1 .....	27
2.2.3 IpgE.....	27
2.3 Crystallisation of Pathogenicity Factors OspD1 and IpgE .....	28
2.4 Homology Modelling of Pathogenicity Factors IpaA and IpgE .....	29
2.5 Summary and Outlook.....	31
2.6 Materials and Methods .....	33
2.6.1 Primers used for PCR amplification of pathogenicity factor genes from the virulence plasmid pCP301 .....	33

2.6.2	Buffers, Enzymes .....	34
2.6.3	Cleavage of the GST-tag .....	34
2.6.4	Homolgy modelling.....	35
2.7	References .....	35
3	Glu <sup>235</sup> is critical for substrate selectivity in TGT .....	39
3.1	Results.....	46
3.1.1	Crystal structure of wild type <i>Z. mobilis</i> TGT in complex with guanine .....	46
3.1.2	Enzymatic characterisation of wild type <i>Z. mobilis</i> TGT.....	47
3.1.3	Construction and enzymatic characterisation of <i>Z. mobilis</i> TGT(Glu <sup>235</sup> Gln) .....	48
3.1.4	Crystal structure analyses of TGT(Glu <sup>235</sup> Gln) .....	49
3.2	Discussion .....	53
3.3	Summary .....	57
3.4	Materials and Methods .....	58
3.4.1	Cloning and TGT preparation .....	58
3.4.2	Preparation of tRNA <sup>Tyr</sup> .....	58
3.4.3	Kinetic parameters .....	58
3.4.4	Crystal structure analyses .....	60
3.4.5	Protein Data Bank Accession Codes .....	62
3.4.6	Crystallographic Tables .....	62
3.4.7	Acknowledgements .....	65

## 1 Introduction

### 1.1 Bacillary dysentery – Shigellosis

Bacillary dysentery, an acute inflammatory bowel disease, is caused by enteroinvasive bacteria of the genus *Shigella*. After oral uptake the bacteria reach the colon, where they have the capacity to invade the colonic and rectal epithelium in humans, thereby causing the acute mucosal inflammation that characterises the disease. This destructive recto–colitis is responsible for the dysenteric symptoms [1].

Shigellosis is spread all–over the world, even though only 1.5 million of the 165.7 million annual cases occur in industrialised countries. The vast majority takes place in developing countries, often epidemically, with a death rate of 1.1 million *p.a.*. Shigellosis is mainly a disease of impoverished people which in about 69 % (112.6 million) of all cases and 61 % (660.000) of all fatalities affects children between the ages of one and five years [2].

#### ***Shigellae* classification**

*Shigellae* are GRAM–negative, nonsporulating, facultative anaerobic bacilli, belonging to the family of *Enterobacteriaceae*. Genetic analysis revealed that *Shigella* belongs to the core of *Escherichia coli* strains [3]. There are four ‘species’ and a varying number of serotypes of *Shigella* [1,2]:

- *Shigella dysenteriae* (16 serotypes), only rarely observed in industrialised countries (1 %). *S. dysenteriae* subtype 1 (“Shiga bacillus”) accounts for brisk and deadly epidemics in the poorest populations, especially in South Asia and sub–Saharan Africa. This subtype produces a potent cytotoxin (Shiga toxin), that is capable to

induce severe inflammations, including kidney, brain, and red blood cell damages [4].

- *Shigella flexneri* (6 serotypes), the most abundant species worldwide, dominating in developing countries with 55 – 85 % (industrialised countries: 16 %).
- *Shigella sonnei* (1 serotype), the most abundant species in industrialised countries (77 %).
- *Shigella boydii* (8 serotypes), less common (6 %) and almost equally distributed all over the world.

## 1.2 Pathogenesis by *Shigellae*

*Shigella* is a highly contagious microorganism. As few as 10 – 100 bacteria can cause the disease in adults. Bacterial dysentery remains essentially limited to the intestinal mucosa, where *Shigellae* are capable to invade and colonise the colon epithelium [1].

The invasion into epithelial cells does not occur through the apical side of the cells, but – after a passage of the colon epithelium's tight junctions *e.g.* via Membranous epithelial cells (M cells), (Figure 2.3, p. 4) [5] – from the basal side (Figure 2.5, p. 4) [6,7].

M cells, specialised to transport antigens (bacteria, *etc.*) through the colon epithelium, present them to associated macrophages. *Shigellae* have the unusual capacity to enter macrophages without damage. After phagocytic uptake, they escape from the phagosome and induce apoptosis of the macrophage. Thus, intact *Shigellae* are released into the mucosa (Figure 2.4, p. 4).

Invasive *Shigellae* induce massive reorganisation of the subcortical cytoskeletal network causing the formation of a macropinocytic vacuole, followed by the entry into the epithelial cells and quick lysis of the endocytic vacuole [8] (Figure 2.6). Escape into the host cytoplasm is followed by an actin-dependent motility process [9]. Once inside the epithelial cells, *Shigellae* propagate and spread to adjacent cells (Figure 1a; Figure 2.6, p. 4) – well protected from immune cells. Infected epithelial cells attract macrophages and polymorphonuclear leucocytes (PMN) from subepithelial tissues. The latter disrupt the integrity of the epithelial barrier and facilitate further *Shigella* invasion from the colon (Figure 2.2 and .7, p. 4).

**Figure 1: Intra- and intercellular spread.**

a) *Shigellae* with actin tails are coloured red<sup>1</sup>. b) IcsA / N-WASP / ARP2/3 mediated intracellular mobility of *Shigella*. G-actin molecules are indicated by brown spheres, F-actin by brown filaments.

In summary, the invasive phenotype of *Shigellae* results in rupture, invasion and destruction of its various cellular targets and finally the mucosal barrier [8,10]. Nevertheless, in contrast to macrophages, PMN are able to kill *Shigellae* inside their phagosomes and eventually cope with the infection [7].

<http://www.med.monash.edu.au/assets/images/microbiology/Shigella.jpg>

**Figure 2: Pathogenesis of *S. flexneri* [7].**

Luminal bacteria invade the colonic epithelial layer by three known mechanisms.

1. *S. flexneri* can manipulate the tight junction proteins expressed by epithelial cells, allowing paracellular movement of bacteria into the sub-mucosa.
2. Polymorphonuclear leucocytes (PMN) cells recruited by IL-8 and IL-1 $\beta$  produced in response to *S. flexneri* invasion create gaps between epithelial cells, through which *S. flexneri* can transmigrate into the sub-mucosa.
3. Endocytic M cells transcytose bacteria, releasing them into an intraepithelial pocket filled with B and T lymphocytes and macrophages.
4. Macrophages phagocytose the bacteria. *S. flexneri* escapes the phagosome and induces the macrophage to undergo apoptosis. The apoptotic macrophage releases IL-1 $\beta$ .
5. Submucosal *S. flexneri* contact the basolateral membrane of epithelial cells, activating secretion of proteins through their type III secretion system. Proteins chaperoned in the cytosol of *S. flexneri* are secreted into the epithelial cell's cytoplasm through a pore formed by IpaB and IpaC. IpaC polymerises actin, IpgD dissociates the plasma membrane from the actin cytoskeleton, VirA destabilises microtubules and IpaA forms a complex with vinculin, depolymerising actin. This creates cell surface extensions which form around the bacterium, driving the epithelial cell to take up *S. flexneri* into a vacuole.
6. IpaB and IpaC lyse the vacuole, releasing *S. flexneri* into the epithelial cell's cytoplasm. The *S. flexneri* protein, IcsA is displayed on only one pole of the bacterium, creating a polymerised actin tail behind the bacterium. This propels *S. flexneri* through the cytoplasm until it contacts the plasma membrane. The force of the contact creates a protrusion into the neighbouring epithelial cell. Both membranes are lysed by IpaB and IpaC, releasing *S. flexneri* into the neighbouring epithelial cell.
7. Intracellular *S. flexneri* induces the epithelial cell to release IL-8. IL-8 and the IL-1 $\beta$  released from apoptotic macrophages are chemotactic to PMN cells (represented by dotted arrows), attracting and inducing them to migrate through the epithelial layer to the lumen. This epithelial disruption amplifies *S. flexneri* invasion of the epithelial layer.

### 1.3 Molecular basis of the *Shigella* invasion mechanism

In *Shigella*, a 220 kb virulence plasmid encodes most of the genes required to express the key steps of the invasive phenotype, enabling cell entry, intracellular mobility, cell spreading and induction of apoptosis [11,12]. The *ipa/mxi-spa* locus, a 30 kb region on the virulence plasmid, is necessary and sufficient to cause entry into epithelial cells *via* macropinocytosis [8]. The virulence factors encoded by this locus facilitate reprogramming of the cellular machinery of epithelial as well as immune cells by activating innate transport and signalling pathways [13,14].

**Figure 3: Entrance structure during *Shigella* invasion.**

Electron microscope image<sup>2</sup>.

Upon contact with the basolateral side of an epithelial cell, the type III secretion apparatus (TTS), a macromolecular structure containing a needle protruding from the bacterial surface [15], delivers *Shigella* effector proteins straight from the bacterial cytoplasm into the cytoplasm of the host cell target. For this purpose, a pore is formed within the cytoplasmic membrane

---

2) [http://biop.ox.ac.uk/www/lea/website/images/shigella\\_invade.jpg](http://biop.ox.ac.uk/www/lea/website/images/shigella_invade.jpg)

by the virulence factors IpaB and IpaC [11] (Figure 2.5, p. 4). In addition, IpaC activates an Src tyrosine kinase and thus a signalling cascade within the host cell, causing actin dependent filopodia and lamellipodia formation, and leading to a macropinocytotic uptake of the bacterium [16] (Figure 3). These events result from a multilateral cross-talk between *Shigella* and host cell signaling pathways which regulate the cytoskeleton, essentially by causing actin nucleation and polymerisation at the eukaryotic cell membrane [14].

Once internalised, the macropinocytotic vacuole is quickly lysed by the bacterium. Thereby it is released into the host cell cytoplasm. The bacterium assembles an F-actin comet at one of its poles enabling mobility within the host cell [17] (Figure 2.6, p. 4), and causing a very efficient process of intra-/intercellular colonisation. This intra-/intercellular spread is a crucial step in the virulence of *Shigella* and is driven by the outer membrane protein IcsA (VirG). This protein is accumulated at the old pole of the bacterial surface and binds to the host cell proteins N-WASP and ARP2/3 leading to a polymerisation of actin, and pushing the bacterium forward inside the host cell [18,19] (Figure 1b, p. 3; Figure 2.6, p. 4).

The described virulence factors are only the most prominent ones among a vast set of further virulence factors involved in the generation of pathogenicity. Below, several pathogenicity factors were selected for a more detailed description of functions.

### **1.3.1 Pathogenicity factor IpaA, its chaperone Spa15 and the host cell protein Vinculin**

Prerequisite for invasion is the TTS mediated translocation of several *Shigella* effector proteins, particularly Ipa (“invasion plasmid encoded antigen”) proteins, to the host cytoplasm [11] (Figure 2.5, p. 4). Among them, IpaA is involved in the maturation of the entry focus [9]. Deletion of its gene does not eliminate the entry capacity, but induces significant attenuation [1].

Expression of the *ipaA* gene occurs independently of the activity of the TTS. Within the bacteria, IpaA is stored in association with the chaperone Spa15 to maintain its secretion-competent state. In the absence of Spa15, IpaA is thought to form premature soluble complexes in the bacterial cytoplasm, preventing IpaA secretion [20]. The crystal structure of dimeric Spa15 has been solved at a resolution of 1.8 Å [21].

**Figure 4: Effect of IpaA on the cytoskeletal rearrangements of the entry focus [9].**

In *ipaA*<sup>-</sup> strains of *Shigella*, uncontrolled polymerisation of actin within the host cell leads to the formation of protrusions, pushing the bacteria away from the cellular surface and thus, hampering invasion. In contrast, in wild-type *Shigella*, cell extensions are not formed in the contact area between bacterium and host cell, promoting an efficient uptake of the bacterium by the host cell.

Cytoskeletal structures are the targets for *Shigella* entry associated proteins like IpaA. To promote a fully functional entry focus, besides the induction of the massive cytoskeletal extensions described above, a control by IpaA is required. If uncontrolled, the formation of these gigantic cell extensions would tend to push the bacterial body away (Figure 4). Actin polymerisation in the contact region of the bacterium and the host cell is avoided by a binding of IpaA to the *N*-terminal head domain of Vinculin [22]. This cytoskeleton-associated protein orchestrates the formation of cell adherence plaques within the host cell, leading to a depolymerisation of available F-actin from adjacent cytoskeletal elements. Thus, a pseudo-adherence plaque is formed [9]. In combination with the cytoskeletal extensions surrounding the bacterial body, a structure is formed that is productive to penetrate. Mutants that do not produce IpaA enter epithelial cells with much lower efficiency than their wild-type counterpart, whereas they induce entry

foci that are larger and much longer lasting than those induced by the wild-type strain (Figure 4) [22]. Entry foci induced by *ipaA* mutants show massive and persistent actin polymerisation, but fail to form the pseudo-adherence plaque that is required for the generation of an endocytic vacuole. Binding of IpaA to the *N*-terminal head domain of Vinculin activates the dormant form of Vinculin and induces its opening, thus revealing a functional actin binding site that participates in the bundling process in its *C*-terminal portion. In addition, this interaction also results in actin depolymerisation (Figure 5).

**Figure 5: IpaA Vinculin interaction.**

Binding of IpaA to the head domain of the host cell protein Vinculin induces opening of Vinculin and F-actin depolymerisation. G-actin molecules are indicated by brown spheres, F-actin by brown filaments.

### 1.3.2 Pathogenicity factor IpgD and its chaperone IpgE

Another pathogenicity factor involved in the maturation of the entry focus is IpgD [23]. Deletion of its gene also does not eliminate the entry capacity of the mutants, but significant reduction of invasion events has been observed [1].

Like IpaA, IpgD is produced independently of TTS activity. Within the bacterial cytoplasm, IpgD is stored in association with its specific chaperone IpgE [23]. IpgE is necessary and sufficient for the stability of IpgD within the cytoplasm. When used to infect tissue culture cells, *ipgD* as well as *ipgE* mutants elicit entry structures that have a different morphology compared with those produced by the wild-type strain [23]. In particular, actin rearrangements induced upon contact of bacteria with epithelial cells are

altered. The mutants provoke fewer actin rearrangements and less membrane ruffling on the cell surface [23].

Phosphoinositides play a central role in the control of several cellular events including actin cytoskeleton organisation. IpgD is translocated into the host cell cytoplasm and acts as a potent inositol-4-phosphatase that specifically dephosphorylates phosphatidylinositol-4,5-bisphosphate [PtdIns-(4,5)P<sub>2</sub>] leading to the accumulation of phosphatidylinositol-5-monophosphate [PtdIns(5)P]. This transformation of PtdIns(4,5)P<sub>2</sub> into PtdIns(5)P by IpgD is responsible for dramatic morphological changes of the host cell, leading to a decrease in membrane tether force associated with membrane blebbing and actin filament remodelling, promoting membrane ruffling at the entry site (Figure 2.5, p. 4). Although IpgD is not absolutely required for entry of bacteria into cultured cells, it is implicated in entry focus formation [23–25]. After secretion, IpgD is thought to form a complex with IpaA within the host cell [23].

### 1.3.3 Pathogenicity factor OspD1

Transcription of several effector genes is regulated by TTS activity which is mediated by the transcriptional activator MxiE as well as by its co-activator IpgC. OspD1 was identified to negatively control expression of these genes regulated by secretion activity. OspD1 associates with the chaperone Spa15 and the activator MxiE and acts as an anti-activator until it is secreted. The TTS activity is induced upon contact of bacteria with host cells. After secretion of OspD1, it cannot longer act as an antiactivator within the bacterial cell which ultimately leads to the transcription of MxiE dependent effector genes [26,27].

### 1.3.4 Pathogenicity factor IpgB2

Because of their ubiquitous role in cell biology, Ras-like small G proteins are a common target for virulence factors secreted by bacterial pathogens [30]. There are well over 100 eukaryotic small G proteins that regulate a myriad of cellular processes including growth, differentiation, membrane trafficking, cytoskeletal organisation, and nuclear import. Several key features of small G proteins allow them to perform these essential functions. First, they act as molecular switches cycling between GTP bound (active) and GDP bound (inactive) conformations. Second, most small G proteins are post-translationally modified. The addition of isoprenoid lipid moieties allows them to associate with specific subcellular compartments. Third, they transmit signaling events in a GTP-dependent manner by activating and/or recruiting downstream target proteins to their sites of action.

IpgB2 subverts host cell signal transduction cascades by mimicking the signaling properties of Ras-like GTPases. It stimulates cellular responses analogous to GTP-active RhoA, a Ras-related GTP binding protein that induces actin stress fiber assembly. IpgB2 neither binds guanine nucleotides nor does it show any sequence similarity corresponding to the conserved GTPase domain, suggesting that it is a functional but not a structural mimic. However, the activity of IpgB2 is dependent on an invariant WxxxE motif found in numerous effectors as targeting sequence. Although the bacterial protein lacks many of the biochemical attributes of GTPases, it induces actin cytoskeletal dynamics in the host cell by stimulating common signaling pathways [31].

### 1.3.5 Pathogenicity factor VirF

The expression of virulence genes is organised hierarchically [32]. Expression of a plasmid encoded key transcription activator for virulence gene expression, namely *virF*, directly activates the transcription of virulence factor

genes like *icsA* and of *virB*. The *virB* gene product then activates the transcription of the *mxi/spa*- and *ipa* genes. Thus, VirF is in the centre of pathogenicity regulation. The amount of VirF depends on various environmental factors, such as pH, osmolarity, temperature and nutrition factors. Below 30° C *Shigella* is not virulent. The *virF* gene transcription is fully activated at 37° C, pH 7.4, physiological osmolarity and in the presence of free amino acids (arginine / methionine). Transcription factors encoded by the bacterial chromosome with expression sensitive to these environmental factors control *virF* expression [32–34]. Apart from this ‘classical’ regulation, the VirF level obviously also depends on an accurate translational machinery [34]. Efficient translation of *virF* mRNA at the ribosome requires the presence of modified tRNA molecules. Modification of tRNA bases is very common in nature [35]. Two modifications were demonstrated to exhibit major influence on the *virF* mRNA translational speed. In specific tRNA molecules the hyper-modified bases queuine in position 34, and 2-methylthio-*N*6-isopentenyladenine in position 37 have to be present. *Shigella* mutants lacking one of these modifications show significantly reduced virulence, approved by mutational studies where gene knock-out in the tRNA modification pathway resulted in the absence of these modifications [36].

#### **1.4 tRNA guanine transglycosylase, the gene product of *vacC* is a target for structure-based drug design**

The *Shigella vacC* gene product, a tRNA guanine transglycosylase (TGT), catalyses the incorporation of a queuine precursor into tRNA at position 34, the anticodon ‘wobble position’. Mutation of the *vacC* gene reduces both, the VirF level as well as the haemolytic activity to 50 – 60 % of the wild-type [34,37]. Thus, tRNA modifying enzymes represent promising targets for the development of antibiotics. Inhibition of such specific tRNA modification steps should result in significantly reduced virulence of *Shigella*. A crystal

structure of the structurally very similar *Zymomonas mobilis* TGT is available [38]. This TGT is employed for structure-based drug design [39–44].

tRNA maturation involves a series of post-transcriptional processing steps resulting in fully functional tRNA molecules. Among these maturation steps nucleoside modification is the most remarkable one. Modifications within or around the anticodon are proposed to fine-tune translational speed and fidelity or to influence the occurrence of frame-shifting events. Nevertheless, the present understanding is still rudimentary [45,46]. *E.g.* only very recently, a putative second function of the *vacC* gene product has been identified. *E. coli* TGT was found to be able to recognise the *virF* mRNA and perform the site-specific modification of a single base. Thus, TGT has been discussed to modulate the VirF translation by a second mechanism, involving a putative riboswitch consisting of the VirF encoding mRNA. A UGU sequence that is specifically recognised by TGTs was identified, exhibiting adjacent sequences (nucleotides 410 – 433 of the *virF* mRNA) that enable the formation of a hairpin structure, similar to the anticodon stemloop of tRNAs [47].

## 1.5 Aims of the project

### 1.5.1 Pathogenicity factors IpaA, IpgE, IpgB2 and OspD1

The roles of many *S. flexneri* virulence genes have been studied in a variety of cell culture experiments such as invasion assays and plaque assays or through the use of *in vivo* animal models [7]. For the present study, the following pathogenicity factors were selected for further analyses, especially concerning the determination of their three dimensional structures: IpaA, IpgE, IpgB2, and OspD1. Therefore, several preceding procedures have to be established, such as cloning and overexpression of the selected genes, protein purification protocols, as well as high throughput screening of crystallisation conditions. Hereafter, the determination of crystal structures of single, or complexed pathogenicity factors should be possible.

Research on *S. flexneri* virulence factors, including structure analyses, will yield further understanding of the molecular basis of *S. flexneri* mediated invasion and destruction of the intestinal mucosa, as well as the role of the host's subsequent innate responses. A comprehensive understanding of *S. flexneri*'s disease-causing mechanisms at the molecular level is essential to develop innovative antipathogenicity molecules against this disease.

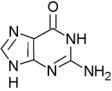

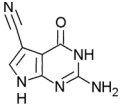

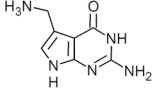

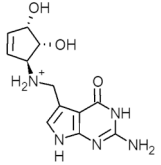

### 1.5.2 Substrate selectivity and specificity study of tRNA guanine transglycosylases of the three domains of life, based on a *Zymomonas mobilis* TGT model system

*Z. mobilis* TGT is an established target for structure-based drug design [39–44]. Nevertheless, TGTs are evolutionary ancient enzymes, present in all three domains of life. The catalytic mechanism is thought to be highly conserved, even if the enzymes exhibit different *in vivo* substrates in a domain-specific manner. *In vitro*, however, 'foreign' substrates are as well

accepted by some of the TGTs. While archeal TGTs are highly selective and accept only guanine and the actual substrate preQ<sub>0</sub>, bacterial TGTs are able to incorporate besides the natural substrate preQ<sub>1</sub> also guanine and preQ<sub>0</sub>. Eukaryotic TGTs are considered as the most unselective enzymes in this context (Table 1). Thus, to be able to specifically inhibit bacterial TGT, it is of high importance to study the selectivity and specificity determining features of these enzymes. *Z. mobilis* TGT was selected to serve as a model system to analyse these features in a mutational study.

**Table 1: *In vivo* and *in vitro* substrates of TGTs of the three domains [42].**

X: *In vivo* substrate; (X): Accepted as a substrate *in vitro*, -: Not accepted as a substrate.

TGT	Exchanged base				
		guanine	preQ <sub>0</sub>	preQ <sub>1</sub>	queuine
Archaeal	G <sup>15</sup>	(X)	X	–	–
Bacterial	G <sup>34</sup>	(X)	(X)	X	–
Eukaryotic	G <sup>34</sup>	(X)	(X)	(X)	X

## 2 Selected *Shigella* Pathogenicity Factors

In cooperation with Johannes Schulze Wischeler [1] and Christian Hasewinkel [2] the pathogenicity factor genes *ipaA*, *spa15*, *ipgB2*, *ospD1*, and *ipgE* were cloned into different plasmid vectors. For some of the pathogenicity factors it is reported that the first 20 *N-terminal* amino acids serve as a signal peptide sequence for TTS secretion or could have a disadvantageous influence on protein solubility due to high hydrophobicity [3–5]. Therefore, for some of the selected genes, the first 60 bp were deleted, leading to shortened versions. In order to find suitable expression systems, several different variants were created. Plasmid constructs leading to the production of tagless, GST-, His6- or Strep-tagged proteins as well as full length and shortened versions were cloned. In addition, it is known that the presence of specific chaperones takes influence on the solubility and stability of these proteins [6–8]. Thus, also co-expression vectors were used. The chaperone Spa15 has been identified to stabilise IpaA [7], and OspD1 [8], while IpgE is known to specifically stabilise IpgD [6]. Additionally, effects of Spa15 on IpgB2 solubility were also analysed. In case of IpaA it was assumed, that co-expression with other interaction partners could avoid aggregation of this pathogenicity factor. Vinculin, the host interaction partner of IpaA, mainly binds with its head domain to this bacterial effector [9,10]. Hence, also the part of the human *vinculin* gene corresponding to the head domain (vinc\_hd) was cloned into the co-expression vector with *ipaA*.

## 2.1 Cloning and Expression of *ipaA*, *spa15*, *vinc\_hd*, *ipgB2*, *ospD1*, *ipgE*

The following pathogenicity factor genes were amplified *via* PCR from the *Shigella* virulence plasmid pCP301 [11] using the primers listed in Table 4 (p. 33): *ipaA*, *spa15*, *ipgB2*, *ospD1*, *ipgE* [1,2]. The plasmid vector pCMV-SPORT6 containing the human *vinculin* gene was purchased from the Deutsche Ressourcenzentrum für Genomforschung GmbH. The first 2,550 bps of the *vinculin* gene encoding the head domain were as well amplified *via* PCR using the primers listed in Table 4 (p. 33). Subsequently, all PCR products were digested with the corresponding restriction enzymes listed in Table 2 (p. 23), purified *via* minispin columns (peQlab) and cloned into the plasmid vectors pPR-IBA2, pET-Duet-1, pGEx-6p-mod [12]. The resulting constructs are listed in Table 2 (p. 23).

In case of *ipgE* first expression experiments had already shown that the expression level is very low, possibly due to rare codon usage. Therefore, three rare codons were changed to codons frequently used in *E. coli* *via* site-directed mutagenesis (primer no. 19–22, Table 4, p. 33) to improve the expression level. Codons of Arg4 (CGA), Leu10 (CTA), Ile11 (ATA) were exchanged by the frequently found *E. coli* codons CGC (Arg4), CTG (Leu10), ATT (Ile11), respectively.

The complete sequences of all final constructs were afterwards checked by MWG Biotech AG, Ebersberg. Subsequently, the constructs were transformed into the following CaCl<sub>2</sub>-competent expression hosts based on BL21 (DE3) and expression levels were checked at 37 °C, 17 °C, and 20 °C, respectively: BL21 (DE3) pLysS, RosettaTM 2, CodonPlus®-RIL, GOLD.

Table 2: Constructs containing the different genes or combinations of genes, expression hosts and levels [1,2].

1) According to diploma theses of Johannes Schulze Wischeler and Christian Hasewinkel [1,2].

2) According to Table 4, p. 11.

3) All expression experiments were performed under the following conditions: 1 mM IPTG, 3 h, 37 °C. Additionally tested conditions are annotated explicitly as follows: **a)** 1 mM IPTG, 6 h, 20 °C; **b)** 1 mM IPTG, 10 h, 17 °C; **c)** 1 mM IPTG, 4 h, 30 °C.

4) In multi cloning site II (MCS II)

5) Codons of Arg<sup>4</sup> (CGA), Leu<sup>10</sup> (CTA), Ile<sup>11</sup> (ATA) were mutated to the frequently found *E. coli* codons CGC (Arg<sup>4</sup>), CTG (Leu<sup>10</sup>), ATT (Ile<sup>11</sup>), respectively (primer numbers: 19-22).

Results of all expression tests are listed in Table 2 (p. 23). In most cases successful overexpression could be obtained but frequently, the resulting protein was present in form of inclusion bodies. Co-expression of *ipaA* and the sequence encoding the Vinculin head domain failed, while co-expression of the chaperone Spa15 had no significant influence on the solubility of IpgB2, OspD1, and IpaA. Similarly, deletion of the first 20 *N-terminal* amino acids seems not to take dramatic influence on protein solubilities. GST-tagging resulted only in case of IpgE in a partially better solubility of the overproduced gene product. In most cases, expression in BL21 (DE3) CodonPlus®-RIL performed best. This expression host provides additional tRNA molecules decoding 'rare codons' thus featuring a higher expression rate for foreign genes with 'unusual codons'.

## 2.2 Purification of Pathogenicity Factors IpgB2, OspD1 and IpgE

Purification of proteins from inclusion bodies is usually performed under denaturing conditions (6 M guanidinium chloride/ 8 M urea) yielding unfolded protein and therefore requires a subsequent refolding step. Thus, in the first attempts only the soluble fractions of expression experiments were further examined. Only in case of IpgB2, OspD1 and IpgE at least partially soluble overexpression products were detected. Hence, these three pathogenicity factors were purified under native conditions.

### 2.2.1 IpgB2

After cell lysis GST-tagged IpgB2 and IpgB2-20 (from production in BL21 (DE3) CodonPlus®-RIL containing plasmid no. 7 (pCH4, Table 2, p. 23), at 1 mM IPTG, 3 h, 37 °C) were purified from the cell lysate by addition of glutathione sepharose, equilibrated in PBS (Phosphate Buffer Saline) and 3 h incubation at 20 °C. After several PBS washing steps, PreScission™ protease

(GE Healthcare) were added to release free IpgB2, and IpgB2–20, respectively, during over night incubation. However, the small amount of protein gained from first expression experiments was not sufficient to successfully observe cleaved, GST-free IpgB2(–20). In addition untagged IpgB2(–20) may be less soluble, compared to the GST-tagged version, putatively leading to its precipitation [2].

### 2.2.2 OspD1

GST-tagged OspD1 (from production in BL21 (DE3) CodonPlus®–RIL containing plasmid no. 11 (527, Table 2, p. 23), at 1 mM IPTG, 3 h, 37 °C) was purified *via* glutathione sepharose, as described for IpgB2. After several PBS washing steps, elution of GST–OspD1 was achieved upon addition of 20 mM glutathione. After a subsequent gel filtration, the sample was concentrated to 6 mg/ml utilising Vivaspin columns (Sartorius), yielding 0.4 mg protein [2].

### 2.2.3 IpgE

GST-tagged IpgE (from production in BL21 (DE3) CodonPlus®–RIL containing plasmid no. 12 (pCH7, Table 2, p. 23), at 1 mM IPTG, 4 h, 30 °C, 2 L culture volume) was purified *via* glutathione sepharose and PreScission™ protease cleavage of the GST-tag, as described for IpgB2. Size exclusion chromatography and concentration of the sample yielded 4.5 mg pure protein at a final concentration of 8 mg/ml. The protein was characterised by MALDI–TOF mass spectrometry (determined mass: 14,433 Da, Figure 6, which is in good agreement with the expected value of 14,455 Da) [2].

**Figure 6: MALDI-TOF mass spectrum of IpgE [2].**

### 2.3 Crystallisation of Pathogenicity Factors OspD1 and IpgE

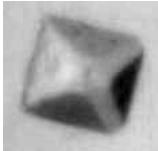

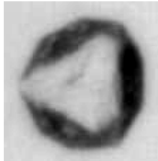

Crystallisation was performed by the vapour diffusion technique at 18 °C. Initial high-throughput screens were set up at the 200 nl scale using a Cartesian pipetting robot and 96-well Greiner sitting drop plates. The following commercial screens were used: Sigma Basic, Sigma Extension, Nextal Classic, Wizard I and II, PEG-Ions.

In case of GST-OspD1, no crystals or crystalline patterns appeared inside the droplets over a period of about 2 month. Nevertheless, in about 50 % of the droplets protein precipitation was observed. Thus, it can be assumed, that the applied protein concentration (6 mg/ml) is basically sufficient for a further screening.

In case of IpgE the conditions listed in Table 3, led to the formation of small crystals [2]. One crystal with a diameter of about 20–50 µm was mounted on a rotating anode X-ray source. Upon radiation, no reflections could be detected. Salt crystals of similar size would have shown few but strong

reflections. Thus, it is likely that these crystals grown under the identified conditions, consist of protein and not salt. However, the crystal size has to be optimised.

**Table 3: IpgE crystallisation conditions identified by highthroughput screening [2].**

Crystal Image	Protein Concentration	Crystallisation Condition	Screen, Well
	4 mg/ml	20 % 1,4-Butandiol 0.2 M Li2SO4 0.1 M MES pH 6.0	Wizard I&II C2
	6 mg/ml	15 % Jeffamin M-600 25 mM CsCl 50 mM MES pH 6.5	Sigma Extension H9
	4 mg/ml	15 % Jeffamin M-600 25 mM CsCl 50 mM MES pH 6.5	Sigma Extension H9

## 2.4 Homology Modelling of Pathogenicity Factors IpaA and IpgE

Since no experimental phases have been determined yet for the above described pathogenicity factors, prospective *de novo* structure determination *via* X-ray methods requires either the production of non-native protein crystals such as seleno methionine or heavy metal derivatives. On the other hand, also a homology model could yield appropriate phases by performing molecular replacement. In that case, structure solution could be performed without the need of synchrotron radiation at variable wavelength.

In case of IpaA and IpgE, homologues with already known crystal structures could be identified in the NCBI GenBank® sequence database [13] *via* BLAST query. The respective Clustal W 1.83 [14] sequence alignments are shown in chapter 5.2.3 (Appendix). Sequence identities of IpaA with a *Salmonella*

*typhimurium* invasion protein (SipA) fragment, and of IpgE with a TTS secretion chaperone of *Salmonella enterica* (SigE) were scored to 29 % (IpaA : SipA), and 24 % (IpgE : SigE). Conserved substitutions were observed in 27 % (IpaA : SipA), and 29 % (IpgE : SigE), leading to a homology of 56 % (IpaA : SipA), and 53 % (IpgE : SigE). Further 15 % (IpaA : SipA), and 14 % (IpgE : SigE) were identified as semi-conserved substitutions, respectively. Based on these sequence alignments, and the crystal structures of the SipA fragment (amino acids 48 – 264, PDB codes 2fm8 – SipA fragment, 2fm9 – SipA fragment in complex with InvB, a TTS chaperone) [15] in case of IpaA, and SigE (PDB code 1k3s – SigE dimer) [16], in case of IpgE respectively, homology models were generated using the program MODELLER [17,18].

The IpaA homology model (fragment of amino acids 48 – 261) shows an  $\alpha$ -helix bundle, consisting of eight helices arranged in a compact fold (Figure 7a). The IpgE homology model exhibits the SigE fold with  $\alpha$ - $\beta$ - $\beta$ - $\beta$ - $\alpha$ - $\beta$ - $\beta$ - $\alpha$  topology [16] (Figure 7b).

**Figure 7: homology models of IpaA and IpgE.**

**a)** IpaA homology model for amino acids 48 – 261 (red) and template structure of *S. typhimurium* SipA, 2fm9, chain A (yellow). **b)** IpgE homology model (blue) and template structure of *S. enterica* SigE, 1k3s, chain A (dark grey) and B (light grey).

## 2.5 Summary and Outlook

The pathogenicity factor genes *ipaA*, *ipgB2*, *ospD1*, *spa15*, and *ipgE* were cloned into several plasmid vectors. In case of *OspD1* and *IpgE* purification protocols could be successfully established. Purified *IpgE* was identified *via* mass spectrometry and crystallisation conditions were detected.

Future attempts should include the following suggestions:

- **IpaA, Spa15, Vinculin head domain:** Codon optimisation, similar to the case of *IpgE* as reported above and separate protein production should be considered. Crystallisation screening should be performed with separated samples as well as with mixed samples to possibly gain crystals of complexes.
- **IpgB2 and OspD1:** Larger expression culture volumes, and purification of the GST-tagged variants should be tried. Crystallisation screening could be carried out with cleaved (tagless), and as well with GST-tagged proteins. GST-tagging obviously does not take sufficient influence on *IpgB2* or *OspD1* solubility. Thus, additionally tagless expression and purification of both *IpgB2* variants, as well as *OspD1* should be carried out directly by refolding from inclusion bodies. This procedure would profit from inclusion body purification, where the overproduced protein is available with rather low amounts of cellular protein impurities. Subsequently, a refolding protocol would have to be established. Several methods such as fast or slow, stepwise or continuous dilution, as well as additive screening (e.g. redox reagents like GSH/GSSG) should be performed.

- **IpgE:** Larger crystallisation droplet volumes have to be tested, hopefully leading to protein crystals large enough and suitable for X-ray structure analysis. Micro- and macroseeding techniques should be attempted, as well as the screening around the identified conditions (e.g. variation of the precipitant's concentration, or the pH of the reservoir solution). If crystals could be gained producing diffraction patterns of sufficient quality upon X-ray radiation, molecular replacement with the homology model, or a poly-alanine model retrieved from the homology model could be carried out. As well, seleno methionine or heavy metal derivatives of the IpgE crystals should be produced in order to determine experimental phases.

## 2.6 Materials and Methods

### 2.6.1 Primers used for PCR amplification of pathogenicity factor genes from the virulence plasmid pCP301

Cloning techniques, expression, protein purification and crystallisation protocols are described in the diploma theses [1,2].

## 2.6.2 Buffers, Enzymes

PreScission <sup>TM</sup> protease	2 u/μl, GE Healthcare
gelfiltration column	HiLoad <sup>TM</sup> 26/60 Superdex <sup>TM</sup> 200 320 mL bed volume
PBS (Phosphate Buffer Saline):	140 mM NaCl 10 mM Na <sub>2</sub> HPO <sub>4</sub> 2.8 mM KCl 1.7 mM KH <sub>2</sub> PO <sub>4</sub> pH 7.3
GST cleavage buffer:	50 mM Tris/HCl pH 7.0 150 mM NaCl 1 mM EDTA 1 mM DTT 0.2 % (v/v) Triton X-100

## 2.6.3 Cleavage of the GST-tag

After cell lysis GST-tagged proteins were purified from 40 ml cell lysate by addition of 2 ml glutathione sepharose, equilibrated in PBS (Phosphate Buffer Saline) and 3 h incubation at 20 °C. After several PBS washing steps,

200 units of PreScission<sup>TM</sup> protease (GE Healthcare) were added with GST cleavage buffer to release free tagless proteins, during over night incubation.

#### 2.6.4 Homolgy modelling

Amino acid sequences were extracted from the deposited crystal structures with PDB codes: 2fm9 (chain A), 2fm8 (chain C), in case of IpaA homolgy modeling, and 1k3s (chains A and B), in case of IpgE homolgy modeling, respectively. These sequences were aligned with the *S. flexneri* IpaA, and IpgE sequences (from SWISS-PROT [19]), respectively, utilising Clustal W 1.83 [14]. The sequences aligned with 29 %, and 24 % identities, respectively. Based on the alignment, ten homology models for IpaA and IpgE were calculated with MODELLER [18]. The best models were selected by picking the model with the lowest value of the MODELLER objective function, which is reported in the second line of the model PDB file.

### 3 Glu<sup>235</sup> is critical for substrate selectivity in TGT

#### Glutamate versus glutamine exchange swaps substrate selectivity in tRNA–guanine transglycosylase: Insight into the regulation of substrate selectivity by kinetic and crystallographic studies<sup>1</sup>

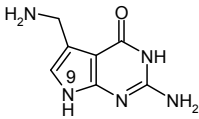

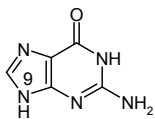

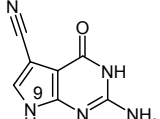

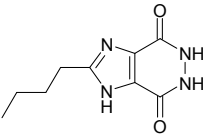

Transfer RNA–guanine transglycosylases (TGT, E.C. 2.4.2.29) constitute a family of tRNA–modifying enzymes present in all three domains of life. They catalyse the base exchange of specific guanine residues in tRNAs by 7–substituted–7–deazaguanines in a domain specific manner [2,3]. Archaeal TGT inserts preQ<sub>0</sub> (for chemical formula see Table 5, p. 40) at position 15 of the majority of known archaeal tRNAs where it is further converted to archaeosine [4]. Bacterial TGT, in contrast, is involved in a pathway introducing the hypermodified base queuine (Q) into the anticodon position 34 (the “wobble position”) of just four different tRNAs [5] (Figure 8, p. 40). These are specific for His, Tyr, Asp and Asn, respectively, and share a U<sup>33</sup>G<sup>34</sup>U<sup>35</sup> sequence in common [6,7]. The enzyme performs the first tRNA dependent step in queuine biosynthesis replacing guanine<sup>34</sup> (G<sup>34</sup>) by preQ<sub>1</sub> [5] (for chemical formula see Table 5, p. 40). This premodified base is produced from GTP [8] by means of the *queC*, *queD*, *queE* and *queF* gene products [9,10]. While the exact functions of QueC, QueD and QueE still have to be figured out, QueF has been identified as an NADPH–dependent oxidoreductase catalysing the reduction of preQ<sub>0</sub> to preQ<sub>1</sub> [11]. After incorporation into tRNA, preQ<sub>1</sub> is converted to the functional Q base in two subsequent steps performed by S–adenosylmethionine:tRNA ribosyltransferase–isomerase (QueA) [12–14] and an unknown coenzyme B<sub>12</sub>–dependent enzyme [15].

<sup>1</sup>) This chapter is extracted from: Tidten N, Stengl B, Heine A, Garcia GA, Klebe G, Reuter K. J Mol. Biol. 2007; 374 (3): 764–76. Mutagenesis was performed by both first authors; enzyme purification, kinetic characterisation and determination of crystal structures 2z1v, 2pwv were performed by Bernhard Stengl; assay modification and determination of crystal structures 2pwu, 2oko, 2pot, 2z1x, 2z1w were performed by Naomi Tidten.

**Table 5: Structures of natural substrates of bacterial TGT and the inhibitor 2-butyl-1*H*-imidazole-4,5-dicarboxylic acid hydrazide (BIH).**

In the line "conformation" the functional group of the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond exposed to the binding pocket is given.

conformation	carbonyl Leu <sup>231</sup> <i>H</i> -bonded Glu <sup>235</sup> (deprotonated)	amide Ala <sup>232</sup> <i>H</i> -bonded Glu <sup>235</sup> (protonated)	amide Ala <sup>232</sup> stacking Glu <sup>235</sup> (protonated)
natural substrates	 <b>preQ<sub>1</sub></b> <i>K<sub>M</sub></i> : 0.7 μM	 <b>guanine</b> <i>K<sub>M</sub></i> : 1.2 μM	 <b>preQ<sub>0</sub></b> <i>K<sub>M</sub></i> : 0.9 μM
inhibitor	 <b>BIH</b> <i>K<sub>ic</sub></i> : 62 μM		

The base exchange catalysed by bacterial TGT follows a ping-pong reaction mechanism [16] which is well documented by crystal structure analyses of TGT from *Zymomonas mobilis* [17–19] (Figure 9, p. 41). In a first step, tRNA binds to TGT and the glycosidic bond of G<sup>34</sup> is cleaved via a nucleophilic attack of Asp<sup>280</sup> producing a covalent TGT•tRNA complex intermediate. Subsequently, preQ<sub>1</sub> replaces guanine within the binding pocket and is incorporated into tRNA in a reverse reaction step. During the base exchange step, replacement of guanine by preQ<sub>1</sub> requires an adjustment of the binding pocket geometry (Figure 9b, c). Both guanine and preQ<sub>1</sub> are recognised by functional groups of Asp<sup>102</sup>, Asp<sup>156</sup>, Gln<sup>203</sup>, and Gly<sup>230</sup>. However, to distinguish between the two bases, a peptide bond formed by Leu<sup>231</sup> and Ala<sup>232</sup> has to flip. G<sup>34</sup>-tRNA binding results in a water mediated contact of the G<sup>34</sup>-N7 to the main chain amide of Ala<sup>232</sup>. Although the moderate resolution of the G<sup>34</sup>-tRNA bound TGT crystal structure does not allow to unambiguously extract this structural detail [18], the structure of TGT bound to the guanine analogous inhibitor 2-butyl-1*H*-imidazole-4,5-

**Figure 8: Queuine modification pathway.**

AdoMet: *S*-adenosylmethionine; B<sub>12</sub>: coenzyme B<sub>12</sub>; oQ: epoxyqueuine.

dicarboxylic acid hydrazide (BIH) (Table 5, p. 40), clearly suggests this binding mode [20]. In order to permit efficient preQ<sub>1</sub> binding the composition of the binding pocket has to be altered. Proper recognition of the preQ<sub>1</sub> amino methyl group requires the *CO* acceptor functionality of the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond to be exposed instead of the *NH* donor (Figure 9c, p. 41). Both peptide bond geometries are stabilised from the protein interior using the side chain carboxyl of Glu<sup>235</sup>, a residue strictly conserved in all bacterial TGTs. Obviously depending on its protonation state, Glu<sup>235</sup> either donates an *H*-bond to the backwards oriented carbonyl oxygen or accepts an *H*-bond from the amide of the flipped peptide bond (Figure 9b, c, p. 41). Consistently, the peptide switch is also observed in crystal structures of the ligand free enzyme in a pH dependent manner. TGT crystals obtained at pH 5.5 show the amide of the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond exposed to the binding pocket [19], while the opposite orientation is observed in crystals obtained at pH 8.5 (Figure 10d, p. 44).

Figure 9: Base exchange mechanism in bacterial TGT.

In addition to preQ<sub>1</sub>, bacterial TGT *in vitro* also accepts the biosynthetic precursor of preQ<sub>1</sub>, namely preQ<sub>0</sub>, as a substrate [19,21]. This substrate promiscuity is a consequence of the above-mentioned peptide switch as binding of preQ<sub>0</sub> is facilitated by the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond conformation required for the accommodation of guanine. Since in bacterial cells both preQ<sub>0</sub> and preQ<sub>1</sub> are present (even at unknown concentrations), bacterial TGT must be able to discriminate between these substrates and preferentially incorporate preQ<sub>1</sub> into tRNA. For *Escherichia coli* TGT there exists evidence that this is achieved through a lower affinity of the enzyme to preQ<sub>0</sub>, since  $K_M$  determination revealed a six-fold higher value for preQ<sub>0</sub>

(2.4  $\mu\text{M}$ ) compared to preQ<sub>1</sub> (0.4  $\mu\text{M}$ ) [21] (for *Z. mobilis* TGT no kinetic data regarding preQ<sub>0</sub> and preQ<sub>1</sub> have been reported yet). Although the available complex structures of preQ<sub>0</sub> and preQ<sub>1</sub> bound to *Z. mobilis* TGT do not provide an ostensible explanation for this selectivity, they reveal some significant differences between the binding modes of the two substrates [19].

In the TGT·preQ<sub>1</sub> complex structure the Glu<sup>235</sup> carboxyl function is clearly present in a deprotonated state, promoting the formation of an *H*-bond (2.8 Å) to the main chain amide of Ala<sup>232</sup>. This results in the exposure of the Leu<sup>231</sup> main chain carbonyl into the binding pocket enabling it to interact with the presumably protonated and thus positively charged amino methyl group of preQ<sub>1</sub> (Figure 10b, p. 44). It should be noted that in this scenario the charges of the Glu<sup>235</sup> carboxylate and the protonated preQ<sub>1</sub> amino methyl group compensate for each other.

In the TGT·preQ<sub>0</sub> complex the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond is flipped compared to the preQ<sub>1</sub> bound situation, *i.e.* the Ala<sup>232</sup> main chain amide is facing the binding pocket, where it *H*-bonds the ligand's acceptor nitrile group. As mentioned above, this conformation of the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond exactly corresponds to the one observed upon binding of the guanine analogue inhibitor BIH. However, the way this conformation is stabilised by the Glu<sup>235</sup> side chain carboxyl, is significantly different. Indeed, the Glu<sup>235</sup> carboxyl function does not *H*-bond in its protonated state the backwards oriented Leu<sup>231</sup> carbonyl. It rather stacks with its hydrophobic  $\pi$  face between the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond and the aromatic ring system of the Tyr<sup>161</sup> side chain. This stacking interaction is stabilised by *H*-bonds formed by the Glu<sup>235</sup> carboxyl group to the main chain amide of Val<sup>233</sup> (3.1 Å) and to the carbonyl oxygen of Gly<sup>230</sup> (2.8 Å). The latter *H*-bond clearly indicates that also here the Glu<sup>235</sup> carboxyl function is present in a protonated state. A shift of the Glu<sup>235</sup> side chain by *ca.* 1.5 Å towards the binding pocket is prerequisite for the stacking interaction. This shift is rendered possible by a

Glu<sup>235</sup>/Gly<sup>236</sup> peptide bond flip which so far had not been observed in any other TGT crystal structure [19] (Figure 10c, e, p. 44).

The present work was aimed to confirm and further analyse the role of Glu<sup>235</sup> in the Leu<sup>231</sup>/Ala<sup>232</sup> peptide switch and in substrate promiscuity of bacterial TGT. In order to mimic a permanently protonated state of the Glu<sup>235</sup> carboxyl function we introduced a conservative Glu<sup>235</sup>Gln mutation into the *Z. mobilis* TGT enzyme. This mutation was expected to firmly fix the peptide switch in its *NH* exposing form independent of the applied pH or any bound substrate. This chapter describes the consequences of this mutation on substrate specificity of *Z. mobilis* TGT as studied by means of enzyme kinetics and crystal structure analyses.

**Figure 10: Crystal structures of bacterial and archaeal TGT.**

- (a) The superposition of bacterial TGT in complex with the TGT inhibitor BIH (*C* atoms in cyan) and guanine (*C* atoms in grey) shows in both cases an identical conformation for the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond stabilised by an *H*-bond of the Leu<sup>231</sup> carbonyl to the protonated Glu<sup>235</sup> side chain carboxyl.
- (b) Bacterial TGT in complex with preQ<sub>1</sub>. The Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond is switched compared to the guanine/BIH bound situation stabilised by an *H*-bond of the Ala<sup>232</sup> amide to the deprotonated Glu<sup>235</sup> carboxyl.
- (c) Bacterial TGT in complex with preQ<sub>0</sub>. The Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond conformation corresponds to that observed for guanine/BIH bound TGT, but stabilisation surprisingly occurs through a stacking interaction with the protonated Glu<sup>235</sup> carboxyl concomitant with a Glu<sup>235</sup>/Gly<sup>236</sup> peptide bond flip.
- (d) Superposition of ligand-free bacterial TGT crystallised at pH 5.5 (*C* atoms in red) and pH 8.5 (*C* atoms in grey). Protonation of Glu<sup>235</sup> at pH 5.5 leads to a binding pocket geometry observed upon binding of guanine/BIH. Deprotonation of Glu<sup>235</sup> at pH 8.5 results in a geometry as induced upon preQ<sub>1</sub> binding.
- (e) Superposition of bacterial TGT and TGT(Glu<sup>235</sup>Gln) both in complex with preQ<sub>0</sub> reveals identical binding pocket geometries. The Glu<sup>235</sup> side chain is stacking between the aromatic ring system of Tyr<sup>161</sup> and the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond (encircled).
- (f) Archaeal TGT with bound preQ<sub>0</sub>. The amide group of the Val<sup>197</sup>/Val<sup>198</sup> peptide bond (corresponding to Leu<sup>231</sup>/Ala<sup>232</sup> in bacterial TGT) is unable to flip. It permanently exposes the Val<sup>198</sup> *NH*, since the opposing Val<sup>197</sup> *CO* is involved in an invariant backbone *H*-bond network.

## 3.1 Results

### 3.1.1 Crystal structure of wild type *Z. mobilis* TGT in complex with guanine

The crystal structure of *Z. mobilis* TGT in complex with the inhibitor 2-butyl-1*H*-imidazole-4,5-dicarboxylic acid hydrazide (BIH) had shown, for the first time, a conformation of the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond, in which the main chain amide of Ala<sup>232</sup> was exposed to the binding pocket [20]. This had been in contrast to all other crystal structures of *Z. mobilis* TGT determined previously, where this peptide bond was oriented such that the main chain carbonyl of Leu<sup>231</sup> was facing the binding pocket. Since guanine just like BIH lacks the exocyclic aminomethyl group of preQ<sub>1</sub>, it had immediately been postulated that binding of guanine to TGT resulted in the same conformation of the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond as binding of BIH. Due to the lack of a high resolution crystal structure of guanine-bound TGT, this assumption had not yet been proven so far. Thus, in order to figure out the exact geometry of the TGT binding pocket with guanine bound, we crystallised *Z. mobilis* TGT in the presence of guanine hydrochloride and determined the complex structure at a resolution of 1.77 Å (Table 7, p. 62). In the electron density map the bound ligand was clearly defined. As observed for the TGT·BIH complex, the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond was present in the *NH* exposing conformation stabilised by a strong *H*-bond (2.4 Å) which was formed between the backwards oriented Leu<sup>231</sup> carbonyl oxygen and the protonated carboxyl group of Glu<sup>235</sup>. Also in absolute accordance with the situation in the TGT·BIH complex an interstitial water was bound *H*-bonding both the Ala<sup>232</sup> main chain amide and the guanine *N7* (Figure 10a, p. 44). Thus, the presented structure confirmed that binding of guanine by TGT leads to the same Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond orientation and Glu<sup>235</sup> conformation as binding of the BIH inhibitor.

### 3.1.2 Enzymatic characterisation of wild type *Z. mobilis* TGT

Since no kinetic data were available for the *Z. mobilis* TGT enzyme regarding preQ<sub>0</sub> and preQ<sub>1</sub> we determined and accordingly redetermined  $k_{\text{cat}}$  and  $K_{\text{M}}$  concerning guanine, preQ<sub>0</sub>, preQ<sub>1</sub> and tRNA. Redetermination of the Michaelis/Menten parameters for guanine and tRNA was done by means of a well established assay monitoring the incorporation of radio-labelled guanine into tRNA [22]. Since no radio-labelled preQ<sub>0</sub> and preQ<sub>1</sub> is commercially available, we used for these substrates a guanine washout assay which in essence was first described by Hoops *et al.* [21]. Here, the decrease of radioactivity in tRNA labelled in position 34 with [8-<sup>3</sup>H]-guanine due to the incorporation of the respective substrate is monitored. The kinetic parameters for all four substrates are summarised in Table 6 (p. 47). With respect to preQ<sub>0</sub> and preQ<sub>1</sub> the six-fold difference in  $K_{\text{M}}$  reported for the *E. coli* enzyme was not observed for *Z. mobilis* TGT. Within the experimental errors the  $K_{\text{M}}$ -values of preQ<sub>0</sub> and preQ<sub>1</sub> were virtually identical and did not differ from that measured for guanine. Instead, the  $k_{\text{cat}}$ -values of preQ<sub>0</sub> and preQ<sub>1</sub> differed significantly by a factor of almost 10. While, compared to guanine, preQ<sub>1</sub> was incorporated into tRNA with a higher rate, the incorporation rate of preQ<sub>0</sub> was substantially lower than that of guanine. Obviously, in contrast to *E. coli* TGT, in *Z. mobilis* TGT the preferred insertion of preQ<sub>1</sub> into tRNA is not achieved by a higher affinity of preQ<sub>1</sub> to the enzyme compared to preQ<sub>0</sub>, but by a clearly higher turnover number.

**Table 6: Kinetic parameters for wild type TGT and TGT(Glu<sup>235</sup>Gln).**

wild type Tgt	tRNA <sup>Tyr</sup> *	[ <sup>3</sup> H]-guanine	preQ <sub>1</sub>	preQ <sub>0</sub>

### 3.1.3 Construction and enzymatic characterisation of *Z. mobilis* TGT(Glu<sup>235</sup>Gln)

To further investigate the influence of the Glu<sup>235</sup> carboxyl on the Leu<sup>231</sup>/Ala<sup>232</sup> peptide switch and thus on substrate selectivity we introduced a Glu<sup>235</sup>Gln mutation into *Z. mobilis* TGT by site directed mutagenesis. The carboxamide of the mutated residue was intended to mimic a permanently protonated and electrically neutral Glu<sup>235</sup> side chain carboxyl. Subsequently, we determined Michaelis/Menten parameters for the mutated enzyme concerning guanine, preQ<sub>0</sub>, preQ<sub>1</sub> and tRNA. The results are summarised in Table 6. As expected, the mutation had no significant influence on the affinity of the tRNA substrate reflected by a virtually unchanged  $K_M$  compared to wild type TGT. A slight increase of  $k_{cat}$  ( $7.0 \cdot 10^{-2} \text{ s}^{-1}$  vs.  $5.4 \cdot 10^{-2} \text{ s}^{-1}$  measured for the wild type enzyme) using guanine as second substrate was not considered significant with respect to the error range of the assay. Alike, the Glu<sup>235</sup>Gln mutation obviously had no influence on the turnover numbers for any of the three substrate bases. The  $k_{cat}$  values regarding guanine, preQ<sub>0</sub> and preQ<sub>1</sub> determined for the mutated enzyme agreed well with those determined for the wild type enzyme. In contrast, however, the mutation caused a measurable change in  $K_M$  with respect to the substrate bases. While  $K_M(\text{guanine})$  was only marginally changed, the most drastical impact of the mutation was observed for  $K_M(\text{preQ}_1)$ . Although this base was still accepted as a substrate,  $K_M$  was increased by a factor of almost 50 suggesting a noticeable decrease in affinity. Unlike guanine and preQ<sub>1</sub>, preQ<sub>0</sub> seemed to bind with an increased affinity to the mutated enzyme as  $K_M$  for this substrate was, compared to wild type TGT, lowered from 0.9  $\mu\text{M}$  to less than 0.5  $\mu\text{M}$ . Due to the slow turnover rate achieved by TGT, in particular with respect to this substrate, an exact determination of  $K_M$  was not possible. To assure an excess of substrate even at low concentrations the amount of enzyme used in the assay would have had to be kept too low to obtain a reasonable signal to noise ratio.

In summary, while the Glu<sup>235</sup>Gln mutation had no significant influence on the turnover number for any of the three substrate bases,  $K_M$  was drastically increased for preQ<sub>1</sub>, marginally elevated for guanine and obviously lowered (even though to an unknown extent) for preQ<sub>0</sub>. Thus, regarding  $k_{cat}/K_M$  as a measure of catalytic efficiency, the Glu<sup>235</sup>Gln mutation resulted in a clearing or even inversion of substrate preference from preQ<sub>1</sub> to preQ<sub>0</sub> (see Table 6, p. 47). This agrees well with the hypothesis, that the Leu<sup>231</sup>/Ala<sup>232</sup> peptide conformation necessary for guanine and preQ<sub>0</sub> accommodation is in wild type TGT stabilised by the protonated state of Glu<sup>235</sup>, which was mimicked by the Glu<sup>235</sup>Gln mutation.

### 3.1.4 Crystal structure analyses of TGT(Glu<sup>235</sup>Gln)

To allow the interpretation of the measured enzyme kinetic data at a structural level, we crystallised the mutated enzyme in its apo form as well as in complex with its substrates and the guanine analogous inhibitor BIH (Table 7, p. 62).

Two structures of ligand-free TGT(Glu<sup>235</sup>Gln) derived from crystals grown at pH 5.5 and pH 8.5, respectively, were determined at nominal resolutions of better than 1.6 Å. In the electron densities of both structures the residues of and near the active site were excellently defined. As expected, in contrast to wild type TGT no pH-dependent conformational change was observed for the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond. Independently whether crystallisation had been performed at pH 5.5 or 8.5, the carbonyl of this peptide bond was oriented backwards while the amide was exposed into the binding pocket. Surprisingly, however, the way this conformation was stabilised by the Gln<sup>235</sup> carboxamide did not correspond to the way it is stabilised by the protonated Glu<sup>235</sup> carboxyl in wild type apo TGT crystallised at pH 5.5. Rather, the geometry of the binding pocket was virtually identical to the one observed in the structure of wild type TGT with preQ<sub>0</sub> bound. No *H*-bond was formed

**Figure 11: Crystal structures of TGT(Glu<sup>235</sup>Gln).**

(a) Superposition of TGT(Glu<sup>235</sup>Gln) in its apo form (crystallised at pH 5.5; the structure obtained at pH 8.5 looks identical) and in complex with preQ<sub>0</sub> reveals equal binding pocket geometries.

(b)  $2|F_o| - |F_c|$  electron density map of TGT(Glu<sup>235</sup>Gln) in complex with guanine contoured at 1.5  $\sigma$  (blue). The green density represents an  $|F_o| - |F_c|$  map with the ligand omitted from the calculation contoured at 3.0  $\sigma$ .

(c)  $2|F_o| - |F_c|$  electron density map of TGT(Glu<sup>235</sup>Gln) in complex with preQ<sub>1</sub> contoured at 1.5  $\sigma$  (blue). The green density represents an  $|F_o| - |F_c|$  map with the ligand omitted from the calculation contoured at 3.0  $\sigma$ . The electron density reveals a split conformation for the Asp<sup>102</sup> side chain indicating an uncomplete occupancy of the binding pocket with the substrate base. The Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond is present in two different conformations. The occupancy of the ligand and of the predominant Leu<sup>231</sup>/Ala<sup>232</sup> and Asp<sup>102</sup> conformers refine to 0.7.

between the Gln<sup>235</sup> carboxamide and the Leu<sup>231</sup> carbonyl oxygen. Instead, the carboxamide stacked between the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond and the side chain aromatic ring system of Tyr<sup>161</sup>. As a consequence, the Gln<sup>235</sup> side chain was shifted towards the binding pocket concomitant with a Gln<sup>235</sup>/Gly<sup>236</sup> peptide flip so far only

observed in preQ<sub>0</sub> bound wild type TGT (with Gln<sup>235</sup> being replaced by Glu<sup>235</sup>). To investigate the influence of a bound substrate on the active-site geometry of TGT(Glu<sup>235</sup>Gln), we determined the crystal structures of the mutated enzyme in complex with preQ<sub>0</sub>, guanine, the BIH inhibitor, and preQ<sub>1</sub>, respectively.

The TGT(Glu<sup>235</sup>Gln)·preQ<sub>0</sub> complex structure was determined at a resolution of 1.70 Å. The electron density for the preQ<sub>0</sub> ligand was clearly defined. Superposition of the TGT(Glu<sup>235</sup>Gln)·preQ<sub>0</sub> complex structure and the structures of the ligand-free mutated enzyme revealed that the binding pocket geometry was virtually identical in all three structures (Figure 11a, p. 50) and exactly corresponded to the one observed in preQ<sub>0</sub> bound wild type TGT (Figure 10e, p. 44). The nitrile nitrogen of preQ<sub>0</sub> was present at a position occupied by a glycerol oxygen picked up from the cryo buffer in the structures of uncomplexed mutated TGT (Figure 11a, p. 50).

The crystal structures of TGT(Glu<sup>235</sup>Gln) in complex with guanine and with the guanine analogous inhibitor BIH were determined at a resolution of 1.80 Å and 1.63 Å, respectively. In both structures the electron densities for the ligands as well as for the residues constituting the binding pockets were excellently defined (for the guanine complex see Figure 11b (p. 50). It was clearly visible that also binding of guanine or BIH did, compared to the apo-form, not result in any conformational change of the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond or of Gln<sup>235</sup>. As in guanine or BIH-bound wild type TGT, the exposed Ala<sup>232</sup> main chain amide formed an *H*-bond to an interstitial water molecule, which was further *H*-bonded to *N*7 of guanine or the corresponding nitrogen of BIH, respectively. In contrast to wild type TGT, however, this conformation was not stabilised by an *H*-bond formed between the Leu<sup>231</sup> carbonyl and the carboxamide of Gln<sup>235</sup> but by a stacking interaction between the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond and the Gln<sup>235</sup> side chain.

In order to understand the way preQ<sub>1</sub> was bound by the mutated TGT we determined the crystal structure of the TGT(Glu<sup>235</sup>Gln)•preQ<sub>1</sub> complex at a resolution of 1.63 Å. Also in this structure the electron density attributable to the ligand was very well defined. A split conformation of the Asp<sup>102</sup> side chain, however, indicated an incomplete occupancy of the binding pocket with preQ<sub>1</sub> (Figure 11c, p. 50). In apo structures of TGT the Asp<sup>102</sup> side chain carboxylate is oriented towards the outside of the binding pocket *H*-bonding the side chain amide of Asn<sup>70</sup> as well as the main chain amide of Thr<sup>71</sup>. Once a substrate base has bound, the Asp<sup>102</sup> side chain rotates into the binding pocket towards the ligand in order to *H*-bond its exocyclic amine at position 3 [23]. In the TGT(Glu<sup>235</sup>Gln)•preQ<sub>1</sub> complex structure *ca.* 30 % of Asp<sup>102</sup> exhibited a side chain conformation pointing towards the outside of the binding pocket suggesting a portion of the binding pocket being unoccupied by the ligand. This was in line with the fact that *K<sub>M</sub>*(preQ<sub>1</sub>) was drastically increased for TGT(Glu<sup>235</sup>Gln). As in all other structures of TGT(Glu<sup>235</sup>Gln) the Gln<sup>235</sup> side chain stacked on top of the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond. Accordingly, the conformation of the Gln<sup>235</sup>/Gly<sup>236</sup> peptide bond remained also here unchanged compared to all other TGT(Glu<sup>235</sup>Gln) structures as well. Interestingly, however, the electron density attributable to the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond could only be interpreted such that it was present in two different conformations. One conformer corresponded exactly to the one observed in the remaining TGT(Glu<sup>235</sup>Gln) structures with the main chain amide of Ala<sup>232</sup> being exposed to the binding pocket. Indeed, this conformation was hardly compatible with a bound preQ<sub>1</sub> molecule due to unfavourable interactions between the Ala<sup>232</sup> main chain amide and the amino methyl group of preQ<sub>1</sub>. The fact that this conformation could be refined to an occupancy of *ca.* 30 % agreed well with the assumption that a portion of the binding pocket was devoid of ligand. In the second conformer the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond was flipped enabling the exposed Leu<sup>231</sup> carbonyl oxygen to *H*-bond the amino methyl group of preQ<sub>1</sub>. This geometry combining the exposed Leu<sup>231</sup> carbonyl with the stacking conformation of

Gln<sup>235</sup> (or Glu<sup>235</sup>) had never been observed in any TGT crystal structure before. As a consequence, exposure of the Leu<sup>231</sup> carbonyl into the binding pocket does not necessarily require the deprotonated carboxyl of Glu<sup>235</sup> *H*-bonding the backwards oriented Ala<sup>232</sup> main chain amide. It is also compatible with a stacking interaction of the Gln<sup>235</sup> side chain, although this mode of stabilisation is obviously energetically less favourable as reflected by the drastically increased  $K_M(\text{preQ}_1)$  measured for TGT(Glu<sup>235</sup>Gln).

## 3.2 Discussion

In this study we have confirmed and further analysed the role of Glu<sup>235</sup> as a general acid/base not directly involved in catalysis but facilitating the binding of various substrates with different *H*-donor and -acceptor properties. The high resolution crystal structure of *Z. mobilis* TGT in complex with guanine presented in this work gives the final proof that binding of each of the three substrate bases (guanine, preQ<sub>0</sub> and preQ<sub>1</sub>) triggers a different geometry of the TGT binding pocket. Prerequisite of the substrate promiscuity observed in TGT is the ability of the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond to flip and thus to change its orientation depending on the bound substrate. Remarkably, the bound substrate not only influences the orientation of this peptide bond but, moreover, the way it is stabilised by the strictly conserved Glu<sup>235</sup>. Obviously, the highly flexible interplay of the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond and the general acid/base Glu<sup>235</sup> facilitates an optimal adaptation of the TGT binding pocket to each of its substrate bases. This is reflected by the virtually identical  $K_M$  values of *Z. mobilis* TGT for guanine, preQ<sub>0</sub> and preQ<sub>1</sub> as determined in this study. Moreover, our results show that the preferred incorporation of the "correct" substrate preQ<sub>1</sub> into tRNA over its biosynthetic precursor preQ<sub>0</sub> is achieved by a *ca.* 10 fold faster turnover rate. It should be noted, however, that to the best of our knowledge it has not been investigated so far, if QueF, the nitrile reductase reducing preQ<sub>0</sub> to preQ<sub>1</sub>, is also acting on preQ<sub>0</sub> incorporated into tRNA. In this case preQ<sub>0</sub> could represent an *in vivo*

substrate of TGT as well. The observed differences in  $k_{\text{cat}}$  for the three substrate bases may hardly be explained by their binding modes observed in the corresponding crystal structures, but possibly may be deduced from their chemical properties. In each case nitrogen  $N9$  of the respective base nucleophilically attacks  $C1$  of the covalently bound tRNA ribose<sup>34</sup> during catalysis (Figure 9c, p. 41 and Table 5, p. 40). In preQ<sub>1</sub> this nitrogen is the most potent nucleophile, as it is in no electronic conjugation with the exocyclic amino methyl group. In guanine,  $N9$  is less nucleophilic due to an electron withdrawing effect of  $N7$  being in conjugation with  $N9$ . The preQ<sub>0</sub> substrate is the least reactive base in this series. Here, the exocyclic nitrile function is conjugated to the endocyclic nitrogen, resulting in an even more pronounced electron withdrawing effect. This is fully consistent with the observed decrease in turnover in the order preQ<sub>1</sub> > guanine > preQ<sub>0</sub>. The virtually identical  $K_M$ -values for the three substrate bases indicate that the conformation of the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond as well as the way it is stabilised by the Glu<sup>235</sup> side chain carboxyl may have little influence on the energetic state of the substrate binding pocket.

With intent to create a bacterial TGT with altered substrate specificity Glu<sup>235</sup> was mutated to Gln in an attempt to mimic a permanently protonated Glu<sup>235</sup> side chain carboxyl. Since the Leu<sup>231</sup>/Ala<sup>232</sup> peptide bond conformation required for the accommodation of preQ<sub>1</sub> involves stabilisation by a deprotonated Glu<sup>235</sup> the mutation was expected to strongly disfavour or even disable preQ<sub>1</sub> binding while leaving unaffected or even improving the binding of guanine and preQ<sub>0</sub>. Kinetic characterisation of TGT(Glu<sup>235</sup>Gln) showed that the change of  $K_M$ (guanine) caused by the mutation was at the border of significance, while  $K_M$ (preQ<sub>0</sub>) was (to an unknown extent) decreased compared to wild type TGT. Although  $K_M$ (preQ<sub>1</sub>) of the mutated enzyme was increased by a factor of almost 50, the remaining affinity to this substrate was still unexpectedly high. The crystal structures of TGT(Glu<sup>235</sup>Gln) in its apo-form as well as in complex with various ligands provided an explanation to the observed kinetic data. The same geometry of the binding pocket was

observed, no matter if the mutated enzyme was crystallised in its apo-form (independent of the applied pH) or in complex with guanine, BIH, or preQ<sub>0</sub>. In each case, the Ala<sup>232</sup> main chain amide was exposed to the binding pocket, stabilised by a stacking interaction with the Gln<sup>235</sup> side chain carboxamide. This conformation was analogous to that observed in wild type TGT bound to preQ<sub>0</sub>. Seemingly, a surprisingly strong *H*-bond formed between the Leu<sup>231</sup> carbonyl and the protonated Glu<sup>235</sup> side chain carboxyl (2.4 Å) plays an important role in stabilising the binding pocket geometry observed in wild type TGT crystallised at pH 5.5 or in complex with guanine/BIH. Due to its less electronegative nitrogen and the presence of two hydrogens over which the positive partial charge is distributed the carboxamide of Gln<sup>235</sup> is obviously not able to form as strong an *H*-bond to the Leu<sup>231</sup> carbonyl rendering the stacking interaction energetically more favourable. Hence, the binding pocket of TGT(Glu<sup>235</sup>Gln) seems predestined for the accommodation of preQ<sub>0</sub>, since independent of any pH no structural rearrangement is required for its binding. *A priori* the binding pocket is present in a geometry identical to the one induced upon preQ<sub>0</sub> binding in wild-type TGT. This finding is supported by the (even though to an unknown extent) reduced  $K_M(\text{preQ}_0)$  determined for TGT(Glu<sup>235</sup>Gln). As a surprise, the crystal structure of TGT(Glu<sup>235</sup>Gln) in complex with preQ<sub>1</sub> revealed a binding pocket geometry featuring an exposed Leu<sup>231</sup> carbonyl stabilised by a Gln<sup>235</sup> stacking interaction. This unexpected geometry showed that the stacking interaction still allows the Leu<sup>231</sup>/Ala<sup>232</sup> peptide flip. As a result, the substrate specificity achieved by the Glu<sup>235</sup>Gln mutation was not as strict as that observed for archaeal TGT which is absolutely unable to bind preQ<sub>1</sub>. It permanently exposes the amide group of the Val<sup>197</sup>/Val<sup>198</sup> peptide bond (corresponding to Leu<sup>231</sup>/Ala<sup>232</sup> in bacterial TGT) allowing both the binding of guanine and of preQ<sub>0</sub> but not of preQ<sub>1</sub>. The peptide flip necessary to accommodate this base is rendered impossible, since the opposing carbonyl of this peptide bond is involved in an invariant backbone *H*-bond network which does not imply the carboxyl group of an acidic amino acid [2,24] (Figure 10f, p. 44).

In summary, the mutated TGT(Glu<sup>235</sup>Gln) investigated in this study behaved in several details different from what was expected, although a more conservative exchange than glutamic acid / glutamine can hardly be performed. The present work clearly shows the indispensability of crystal structure analyses for the correct interpretation of kinetic data obtained from mutated proteins.

Furthermore, this study provides an example that mutation of a residue which does not even directly interact with any ligand enables the inversion of substrate selectivity of an enzyme. This may generally underline the importance to consider residues in the "second sphere" of binding pockets during attempts of creating enzymes with new binding properties.

The successful modulation of selectivity is an important step towards the understanding of selectivity and specificity determining features in TGTs. In *E. coli* TGT replacement of Asp<sup>156</sup> (*Z. mobilis* numbering) by Asn altered the specificity towards xanthine even though at the expense of a reduced catalytic activity [25]. In this context it might be interesting to study mutational exchanges in the close neighbourhood of the attacking nucleophile Asp<sup>280</sup>. In bacterial TGT this residue is tightly kept in position by *H*-bonds formed with Gly<sup>261</sup> and Tyr<sup>258</sup> [18]. In archaeal TGT the tyrosine is replaced by a strictly conserved histidine [2]. Likely, this exchange will have pronounced influence on the catalytic properties.

These considerations provide a perspective towards an ambitious goal: the modification of substrate specificity towards bases other than preQ<sub>0</sub> or preQ<sub>1</sub> and their efficient incorporation into the wobble position of tRNAs. This would allow to study the translational process in more detail via well designed modulation of the accuracy of the wobble base pairing.

### 3.3 Summary

Bacterial tRNA–guanine transglycosylase (TGT) catalyses the exchange of guanine in the wobble position of particular tRNAs by the modified base preQ<sub>1</sub>. *In vitro*, however, the enzyme is also able to insert the immediate biosynthetic precursor, preQ<sub>0</sub>, into those tRNAs. This substrate promiscuity is based on a peptide switch in the active site, gated by the general acid/base Glu<sup>235</sup>. The switch alters the properties of the binding pocket to allow either the accommodation of guanine or preQ<sub>1</sub>. The peptide conformer recognising guanine, however, is also able to bind preQ<sub>0</sub>. To investigate selectivity regulation, kinetic data for *Z. mobilis* TGT were recorded. They show that selectivity in favour of the actual substrate preQ<sub>1</sub> over preQ<sub>0</sub> is not achieved by a difference in affinity but via a higher turn-over rate. Moreover, a TGT(Glu<sup>235</sup>Gln) variant was constructed. The mutation was intended to stabilise the peptide switch in the conformation favouring guanine and preQ<sub>0</sub> binding. Kinetic characterisation of the mutated enzyme revealed that the Glu<sup>235</sup>Gln exchange has, with respect to all substrate bases, no influence on  $k_{\text{cat}}$ . In contrast,  $K_{\text{M}}(\text{preQ}_1)$  is drastically increased while  $K_{\text{M}}(\text{preQ}_0)$  seems to be decreased. Hence, regarding  $k_{\text{cat}}/K_{\text{M}}$  as an indicator for catalytic efficiency, selectivity of TGT in favour of preQ<sub>1</sub> is abolished or even inverted in favour of preQ<sub>0</sub> for TGT(Glu<sup>235</sup>Gln). Crystal structures of the mutated enzyme confirm that the mutation strongly favours the binding pocket conformation required for the accommodation of guanine and preQ<sub>0</sub>. The way this is achieved, however, significantly differs from what was predicted based on crystal structures of wild type TGT.

### 3.4 Materials and Methods

#### 3.4.1 Cloning and TGT preparation

The QuikChange™ site-directed mutagenesis kit (Stratagene) was used to introduce a Glu<sup>235</sup>Gln mutation into the wild type *tgt* expression plasmid pET9d-ZM4 [26] following the vendor's protocol. The primers used for mutagenesis were E235Q-s (5'-GGG GGA TTG GCT GTG GGT CAA GGA CAG GAT GAA ATG-3') and E235Q-a (5'-CAT TTC ATC CTG TCC TTG ACC CAC AGC CAA TCC CCC-3') (mutation underlined). Sequencing of the entire *tgt* gene (MWG Biotech, Ebersberg) confirmed the presence of the desired mutation as well as the absence of any further unwanted mutation. Subsequently, the mutated plasmid pET9d-ZM4-E235Q was transformed into *E. coli* BL21 (DE3) pLysS cells. These cells were used for the preparation of the TGT enzyme following the method described by Romier *et al.* [27].

#### 3.4.2 Preparation of tRNA<sup>Tyr</sup>

Preparation of *E. coli* tRNA<sup>Tyr</sup> (ECY2) *via* in vitro transcription was done following the method described by Curnow *et al.* [28].

#### 3.4.3 Kinetic parameters

Kinetic parameters for TGT and TGT(Glu<sup>235</sup>Gln) have been determined for the different substrates essentially as described in Meyer *et al.* [22].

Michaelis-Menten parameters for tRNA and guanine were determined monitoring incorporation of radioactively labelled guanine into tRNA<sup>Tyr</sup> in position 34. Kinetic data for both substrates were determined separately in triplicate and average values were calculated. Kinetic parameters for guanine were measured using 150 nM TGT, 15 µM unlabelled tRNA<sup>Tyr</sup>, and variable

concentrations of [8-<sup>3</sup>H]-guanine (0.9 Ci/mmol,; Hartmann Analytic) in the range of 0.5 – 20  $\mu$ M in buffer solution (200 mM HEPES pH 7.3, 20 mM MgCl<sub>2</sub>) and 2.95  $\mu$ M ( $\equiv$  5 % of critical micellar concentration) Tween 20 (Roth). Kinetic parameters for tRNA were measured using 150 nM TGT, 20  $\mu$ M [8-<sup>3</sup>H]-guanine, and variable concentrations of tRNA<sup>Tyr</sup> (0.25 – 15  $\mu$ M). Initial velocities of the base exchange reaction in counts per minute were converted to [ $\mu$ M/min] using a calibration constant derived from liquid scintillation counting of [8-<sup>3</sup>H]-guanine solutions with variable concentrations. Kinetic parameters were determined via double-reciprocal linearisation using the method of Eadie-Hofstee and linear regression using GraFit [29].

Michaelis-Menten parameters for preQ<sub>0</sub> and preQ<sub>1</sub> were calculated *via* monitoring the loss of [8-<sup>3</sup>H]-guanine from tRNA<sup>Tyr</sup> radio-labelled in position 34. To produce radioactively labelled tRNA 50  $\mu$ M unmodified tRNA<sup>Tyr</sup> was incubated with 0.5  $\mu$ M TGT and 10  $\mu$ M [8-<sup>3</sup>H]-guanine (11.8 Ci/mmol, Hartmann Analytic) in TGT assay buffer for 2 h. TGT and free guanine/ [8-<sup>3</sup>H]-guanine were extracted from the reaction mixture by the addition of equal volumes of Roti-Phenol (Roth) and chloroform : isoamylalcohol (24:1). The aqueous supernatant was once more treated with an equal volume of chloroform : isoamylalcohol (24:1). From the aqueous supernatant containing the radioactively labelled tRNA samples were retained to determine the specific activity of the radio-labelled tRNA. An additional purification step was performed via gel filtration using NAP-columns (GE Healthcare, Life Science) and TGT assay buffer. From the eluted solution again samples were retained to derive the final concentration of the radio-labelled tRNA from its specific activity. For each preparation it amounted to *ca.* 20  $\mu$ M. Kinetic parameters for preQ<sub>0</sub> and preQ<sub>1</sub> were measured using 150 nM wild type TGT or TGT(Glu<sup>235</sup>Gln) and 8  $\mu$ M radio-labelled tRNA<sup>Tyr</sup>. The concentration of preQ<sub>0</sub> was varied in a range of 0.5 – 15  $\mu$ M. For preQ<sub>1</sub> variable concentrations in a range of 0.5 – 15  $\mu$ M for wild type TGT and 2 – 80  $\mu$ M for TGT(Glu<sup>235</sup>Gln) were applied. Initial velocities in counts per minute were calculated from the decreasing tritium labelling level of tRNA due to the

incorporation of the respective substrate bases. Initial velocities in counts per minute were converted to [ $\mu\text{M}/\text{min}$ ] using a calibration constant derived from liquid scintillation counting of guanine/ [ $8\text{-}^3\text{H}$ ]-guanine solutions with variable concentrations. Kinetic parameters were determined *via* double-reciprocal linearisation using the method of Eadie-Hofstee and linear regression using GraFit [29].

#### 3.4.4 Crystal structure analyses

TGT(Glu<sup>235</sup>Gln) crystals suitable for ligand soaking were produced in a two step procedure. Droplets were prepared by mixing 2  $\mu\text{L}$  of concentrated protein solution (14 mg/mL) with 2  $\mu\text{L}$  reservoir solution [100 mM MES, pH 5.5, 1 mM DTT, 13 % (w/v) PEG 8,000, 10 % (v/v) DMSO]. Micro-crystals were grown at 291 K using the hanging-drop vapour diffusion method in the presence of 1.0 mL of reservoir solution of the respective seeding buffer. Micro crystals grew within two weeks.

Subsequently, macro-seeding was performed under similar conditions to obtain crystals of the uncomplexed protein. Again droplets were prepared by mixing 2  $\mu\text{L}$  of concentrated protein solution with 2  $\mu\text{L}$  macro-seeding reservoir solution [100 mM MES, pH 5.5, 1 mM DTT, 8 % (w/v) PEG 8,000, 10 % (v/v) DMSO]. One micro-crystal was transferred into this solution. Single crystals with a size of approximately  $0.7 \times 0.7 \times 0.2 \text{ mm}^3$  grew within two to four weeks.

To obtain crystals of apo-TGT(Glu<sup>235</sup>Gln) at pH 8.5, buffers were used identical to those described above but with 100 mM Tris/HCl pH 8.5 instead of 100 mM MES pH 5.5 as buffer system.

To allow co-crystallisation of the mutated TGT in complex with preQ<sub>0</sub> the compound was dissolved in DMSO and added to the macro-seeding droplet to a final concentration of 20 mM. Crystals of mutated TGT complexed to

preQ<sub>1</sub>, BIH and guanine as well as crystals of wild type TGT bound to guanine were produced by a soaking procedure. The compounds were dissolved in DMSO and added to 2  $\mu$ L of a crystallisation droplet to a final concentration of 10 to 20 mM. Finally, a single TGT crystal was transferred into the droplet and soaked for 30 min.

For data collection, crystals were cryoprotected using glycerol. The glycerol and PEG 8,000 concentrations of the macro-seeding buffers were increased stepwise by transferring the crystals to six different 2  $\mu$ L cryo-droplets each with 5 to 30 min incubation times [glycerol concentrations (v/v): 5 %  $\rightarrow$  10 %  $\rightarrow$  15 %  $\rightarrow$  20 %  $\rightarrow$  25 %  $\rightarrow$  30 %; and PEG 8,000 concentrations (w/v): 5.0 %  $\rightarrow$  6.3 %  $\rightarrow$  7.5 %  $\rightarrow$  8.0 %  $\rightarrow$  8.8 %  $\rightarrow$  9.8 %, respectively]. These droplets also contained the ligands at equivalent concentrations compared to soaking and co-crystallisation conditions. The cryo-soaked crystals were flash-frozen in liquid N<sub>2</sub>. Data sets were collected at cryo conditions (100 K) with CuK $\alpha$  radiation ( $\lambda = 1.5418$  Å) using a Rigaku RU-300 rotating-anode generator at 50 kV and 90 mA equipped with Xenocs focussing optics and an R-Axis IV detector. All crystals tested exhibited monoclinic symmetry in space group C2 containing one monomer per asymmetric unit with Matthews coefficients of 2.3 – 2.4. Data processing and scaling was performed using the HKL2000 package [30]. For all refined structures unit cell dimensions for the crystals, data collection and processing statistics are given in Table 7.

For crystals grown at pH 5.5 coordinates of the apo TGTt crystal structure grown at pH 5.5 (PDB-code: 1P0D) were directly applied for initial rigid-body refinement of the protein molecule followed by repeated cycles of conjugate gradient energy minimisation, simulated annealing and B-factor refinement using the CNS program package [31]. For the crystal grown at pH 8.5 the coordinates of the apo TGT crystal structure grown at pH 8.5 (PDB-code: 1PUD) were applied. Refinement at the later stages for all other structures was performed with SHELXL [32]. Here, up to 50 cycles of conjugate gradient minimisation were performed with default restraints on bonding geometry

and B-values: 5 % of all data were used for  $R_{\text{free}}$  calculation. Amino acid side chains were fit to  $\sigma A$ -weighted  $2|F_o| - |F_c|$  and  $|F_o| - |F_c|$  electron density maps using Coot [33]. Water, glycerol molecules, and ligands were located in the difference electron density and added to the model for further refinement cycles. Anisotropic conjugate gradient refinement resulted in a significant improvement of the models built for apo TGT(Glu<sup>235</sup>Gln) (pH 5.5 and 8.5), TGT(Glu<sup>235</sup>Gln)•BIH, and TGT(Glu<sup>235</sup>Gln)•preQ<sub>1</sub>. During the last refinement cycles, riding  $H$ -atoms were introduced for the protein residues (not for the ligand) without using additional parameters. All final models were validated using PROCHECK [34]. Data refinement statistics are given in Table 7.

### 3.4.5 Protein Data Bank Accession Codes

The following Protein Data Bank (PDB) accession codes were allocated to the crystal structures determined during this work (also given in Table 7):

TGT•preQ <sub>0</sub> : <b>2QII</b>	TGT(Glu <sup>235</sup> Gln)•guanine <b>2POT</b>
TGT•guanine: <b>2PWU</b>	TGT(Glu <sup>235</sup> Gln)•BIH <b>2Z1W</b>
TGT(Glu <sup>235</sup> Gln) pH 5.5: <b>2OKO</b>	TGT(Glu <sup>235</sup> Gln)•preQ <sub>0</sub> <b>2PWV</b>
TGT(Glu <sup>235</sup> Gln) pH 8.5: <b>2Z1V</b>	TGT(Glu <sup>235</sup> Gln)•preQ <sub>1</sub> : <b>2Z1X</b>

### 3.4.6 Crystallographic Tables

**Table 7: Crystallographic data collection and refinement statistics.**

- a) number in parentheses is for highest resolution shell
- b)  $R(I)_{\text{sym}} = \sum |I - \langle I \rangle| / \sum I$  with  $I$  representing the observed intensities and  $\langle I \rangle$  representing the mean observed intensity
- c)  $R_{\text{work}} = \sum_{hkl} |F_o - F_c| / \sum_{hkl} |F_o|$ .
- d)  $R_{\text{free}}$  was calculated as for  $R_{\text{work}}$  but on 5 % of the data excluded from the refinement.

## 4 Characterisation of a model system for the human TGT binding pocket

### 4.1 Introduction

Transfer RNA-guanine transglycosylases (TGTs, EC 2.4.2.29), evolutionary ancient enzymes, are involved in the hypermodification of tRNAs [1]. TGTs catalyse a base exchange reaction, excorporating a certain guanine base within specific tRNAs and introducing 7-substituted-7-deazaguanines [1,2]. The enzymes are found in all three domains of life. Although distinct bases are incorporated into tRNA in a domain-specific manner, the catalytic subunits of TGTs are structurally well conserved [2].

The molecular differences of archaeal and bacterial TGTs have been discussed in chapter 3. As described, archaeal TGTs exchange a guanine base at position 15 within the D-arm of tRNAs and are involved in a hypermodification pathway, finally leading to archaeosine-tRNAs [3] (Table 8). In contrast, in bacteria and eukaryotes, guanine<sup>34</sup> of the tRNA anticodon loop is exchanged and the final hypermodification product within the tRNAs is the base queuine (Table 8). Nevertheless, bacterial and eukaryotic TGTs still differ in their *in vivo* substrate bases (Table 8). Bacterial TGTs incorporate a relatively small modified base, namely preQ<sub>1</sub>, which is afterwards further modified to the functional queuine within the tRNA by S-adenosylmethionine:tRNA ribosyltransferase-isomerase (QueA) [4–6] and an unknown coenzyme B<sub>12</sub>-dependent enzyme [7]. In contrast, eukaryotic TGTs directly incorporate queuine into their tRNA substrates [8]. In bacteria and eukaryotes, most likely, the translational properties of the tRNA substrates are influenced by these modifications [9,10].

**Table 8: Three domains of life: Final tRNA modifications and substrate bases of TGTs.**

TGT	Archaeal	Bacterial	Eukaryotic
Exchanged base	G <sup>15</sup>	G <sup>34</sup>	G <sup>34</sup>
Substrate base	 preQ <sub>0</sub>	 preQ <sub>1</sub>	 queuine
Final tRNA modification	 archaeosine	 queuine	 queuine

An evolutionary highly conserved mechanism is assumed to originate from an ancient ancestor that existed even before the separation of the three domains [2]. Bacterial TGTs have been well characterised by extensive kinetic studies and crystal structure analyses of *Zymomonas mobilis* TGT [11–16]. Four specific tRNA substrates are known: tRNA<sup>Tyr, Asp, Asn, His</sup>, sharing a common U<sup>33</sup>G<sup>34</sup>U<sup>35</sup> sequence [17,18]. The TGT catalysed reaction follows a ping-pong mechanism [19]. First, the tRNA substrate binds to the enzyme and Asp<sup>280</sup> (*Z. mobilis* numbering) performs a nucleophilic attack, cleaving the *N*-glycosidic bond of guanine<sup>34</sup> at the wobble position of the anticodon loop and producing a covalent TGT · tRNA intermediate complex [20]. Subsequently, the modified base preQ<sub>1</sub> [21] (Table 8) replaces guanine within the binding pocket. In a reverse reaction step, it is incorporated into tRNA (Figure 9, chapter 3).

Bacterial TGTs are homodimers of approximately 43 kDa per monomer [22]. In contrast, mammalian TGTs appear to be composed of a heterodimer [23]

consisting of one approximately 60 kDa subunit, and one smaller, presumably the catalytic subunit. In *Homo sapiens*, this 44 kDa subunit shows high homology to bacterial TGTs (43 % sequence identity between *H. sapiens* and *Z. mobilis* [24]). In addition, a homology model based on *Z. mobilis* TGT and the *Caenorhabditis elegans* sequence (38.4 % sequence identity) indicate a very high structural similarity of the active sites of bacterial and eukaryotic TGTs (five of seven active site residues are strictly conserved) [25].

Mutation of the *tgt* gene in *Shigella flexneri* results in a significant loss of pathogenicity of the bacterium [26]. *Shigellae* are the causative agents of bacterial dysentery and effect some 600,000 infant deaths per year, mainly in developing countries with sub-standard hygiene and water supplies. Extensive studies of *S. flexneri* have resulted in a detailed understanding of the pathogenesis, involving bacterial invasion into colonic epithelial cells followed by intracellular multiplication and spreading into adjacent cells [27]. The virulence was shown to be multifactorial and is under control of various genes encoded by the chromosome and the large virulence plasmid [28]. Mutation of the *tgt* gene causes a reduced synthesis of the VirF protein, a key regulatory protein for the full expression of virulence. This effect is a consequence of the less efficient translation of the *virF* mRNA, presumably due to the absence of modified tRNA molecules [26] or a putative riboswitch-like function of the *virF* mRNA itself [29]. TGT has been suggested to be able to modify the *virF* mRNA as well, thereby influencing its translation competent conformation [29]. In any case, TGT is essentially required by the bacterium to produce the virulence factor VirF and its pathogenic phenotype. Therefore, TGT has been established as a target for structure-based drug design [30].

Queuine modification is thought to affect the speed and accuracy of the translational process and was reported to exhibit pleiotropic effects on cellular metabolism [1]. Hence, to be able to specifically inhibit the bacterial

target while having unaffected the human counterpart, it is of utmost importance to study selectivity-determining features.

To date, no crystal structure of an eukaryotic, in particular of human TGT (hTGT) is yet available, although multiple sequences of eukaryotic TGTs resulting from several genome projects [24,31,32] have been deposited during the last years. So far, not even the heterologous production of an active eukaryotic TGT could be achieved. Rather, the human TGT catalytic subunit was reported to be toxic to *E. coli* rendering the isolation of an active catalytic subunit of mammalian TGT impossible [24].

Hitherto, the *C. elegans* TGT homology model is the only source for a comparison of eukaryotic and bacterial TGT active sites in structural terms [25]. Romier *et al.* discussed that most presumably a spatial expansion of the binding pocket in eukaryotic TGTs enables the binding of extended preQ<sub>1</sub>-like substrates such as queuine. This enlargement of the binding pocket was discussed to be due to an eukaryote-specific Val<sup>233</sup>Gly (*Z. mobilis* numbering) replacement. A further Cys<sup>158</sup>Val replacement was suggested to facilitate additional van der Waals contacts to the cyclopentenyl moiety of queuine [25].

The aim of this project is to study the differences between bacterial TGT as a drug design target and human TGT as the host's counterpart. In this study, based on *Z. mobilis* TGT a genetically engineered model system for human TGT was designed, to probe the properties of such an extended binding pocket.

## 4.2 Results

### 4.2.1 Sequence comparisons and homology modelling

Until now, structural information of eukaryotic TGTs was only gained from a homology model of the *C. elegans* enzyme [25]. However, in recent years, a large number of eukaryotic TGT sequences have been deposited [24,31,32]. Since the human TGT sequence is now available [24], a homology model was constructed for human TGT based on *Z. mobilis* TGT crystal structures. The sequences were aligned utilising Clustal W 1.83 [33] (chapter 5.2.1, Appendix). Based on this alignment, ten homology models for human TGT were generated with MODELLER 6a [34,35]. The best scored model is shown in Figure 12b. It can be clearly seen that the residues inside the binding pocket are in general highly conserved among bacterial and eukaryotic TGTs (Figure 12a). As in the *C. elegans* TGT homology model [25], also in the human TGT model, a Val<sup>233</sup> (*Z. mobilis* numbering)/ Gly<sup>216</sup> (human TGT numbering) exchange can be identified as the crucial difference between the human and bacterial TGT binding pockets. This leads to an enlarged binding pocket which is required for queueine binding. The replacement of Cys<sup>158</sup>/Val<sup>145</sup> is observed as well (Figure 12a, b). Thus, as expected, considerations of Romier *et al.* [25] for the *C. elegans* model are also found for the human TGT homology model. It has already been reported that the Val<sup>233</sup>/Gly<sup>216</sup> and Cys<sup>158</sup>/Val<sup>145</sup> replacements are highly conserved among the bacterial and eukaryotic domains [25], respectively. Taking into account the newly deposited sequences in a multiple sequence alignment of 100 bacterial, and 100 eukaryotic TGT sequences, Val<sup>233</sup> is found to be strictly conserved among bacteria, while Gly<sup>216</sup> is to 79 % present in eukaryotes. The conservation of Cys<sup>158</sup> (99 %) in bacterial, and also of Val<sup>145</sup> (59 %) in

**Figure 12: Homology modeling.**

eukaryotic TGTs is sufficiently high to consider these two sites as characteristic for the respective domains (chapter 5.2.2, Appendix). Both sites were therefore chosen for a mutational study, in order to generate a model for the human TGT binding pocket based on the well established *Z. mobilis* TGT system. The mutated bacterial TGT was expected to accommodate queuine and to give new insights into the substrate recognition properties of human TGT.

#### 4.2.2 Construction and enzymatic characterisation of *Z. mobilis* TGT variants

*Z. mobilis* TGT, serving as the basis for this mutational study, exhibits one residue within the active site, that is unique among bacteria: Tyr<sup>106</sup>. Usually, at the corresponding position a phenylalanine is found in nearly all bacterial TGTs. With 99 % it is very highly conserved. Brenk *et al.* had already shown, that a Tyr<sup>106</sup>Phe TGT variant exhibits no significant changes of the enzymatic properties [14]. In eukaryotic TGTs a phenylalanine at the corresponding position (Phe<sup>93</sup> in human TGT) is as well conserved to 65 %. Thus, to generate a model system as authentic as possible, the *Z. mobilis tgt* gene, already carrying the Tyr<sup>106</sup>Phe mutation, was chosen as template for site-directed mutagenesis. Since the Tyr<sup>106</sup>Phe replacement does not affect the enzyme's properties [14], in the following, this mutation as it is considered in all studies will not be mentioned explicitly.

To study the significance of residues Cys<sup>158</sup> (Val<sup>145</sup> in human TGT) and Val<sup>233</sup> (Gly<sup>216</sup> in human TGT) with respect to substrate specificity, a Cys<sup>158</sup>Val variant (named TGT(C<sup>158</sup>V) in the following), a Val<sup>233</sup>Gly variant (named TGT(V<sup>233</sup>G) in the following), and a Cys<sup>158</sup>Val/Val<sup>233</sup>Gly variant (named TGT(C<sup>158</sup>V/V<sup>233</sup>G) in the following) were created by site-directed mutagenesis of the *tgt*-Y106F template. All different variants could be produced and purified according to standard protocols [12,36].

Subsequently, to be able to compare the enzymatic properties of the variants with the wild-type enzyme, kinetic measurements were performed by means of a well established assay detecting the incorporation of [8-<sup>3</sup>H]-guanine in exchange with the native guanine<sup>34</sup> from the tRNA substrate. All variants were active at the level of detection. While the  $K_M$  values for guanine and tRNA remained almost unchanged within the experimental error (Table 9, p. 77),  $k_{cat}$  was significantly decreased in all variants compared to the wild-type enzyme. In case of the TGT(C<sup>158</sup>V) variant, the turnover number was decreased by factors of 3–5, while in case of the TGT(V<sup>233</sup>G) variant it was decreased by a factor of about one order of magnitude, and by almost two orders of magnitude for TGT(C<sup>158</sup>V/V<sup>233</sup>G).

Surprisingly, all exchanged residues, which are fairly distant from the catalytic residue Asp<sup>280</sup> (Figure 12, p. 74), seem to take a dramatic influence on the catalytic activity, even though affinity towards the substrates remains almost unchanged.

A further comparison of the human and bacterial TGT binding pockets (Figure 12, p. 74) reveals a third residue, which is as well quite proximate to the substrate and differs in the two TGTs: Ala<sup>232</sup> (*Z. mobilis* numbering) is indeed not strictly conserved (63 %) among bacteria. In about 37 % of the remaining cases Ser<sup>232</sup> is found which corresponds to Ser<sup>216</sup> in the human TGT. In eukaryotes this residue is conserved to 51 %. Thus, to examine, whether this residue is required by an enlarged binding pocket for efficient enzyme activity, two additional variants were generated: TGT(A<sup>232</sup>S/V<sup>233</sup>G), and TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G). Kinetic characterisation of the newly generated variants revealed, however, that the Ala<sup>232</sup>Ser exchange has no significant influence on catalytic activity (Table 9).

Next, incorporation of preQ<sub>1</sub> and queuine into tRNA was analysed. Currently, no radio-labelled preQ<sub>1</sub> and queuine are commercially available. Thus, a ‘reverse assay strategy’ as already described previously [16,37] was

performed. There, the decrease of radioactivity in  $[8-^3H]$ -guanine<sup>34</sup>-tRNA is monitored in consequence of the replacement of the labeled guanine by the respective substrate.

**Table 9: Kinetic charcteriation of the TGT variants.**

wild-type TGT	tRNA <sup>Tyr</sup> *	$[8-^3H]$ -guanine	preQ <sub>1</sub>

Wild-type TGT and variants characterised with substrates tRNA<sup>Tyr</sup>,  $[8-^3H]$ -guanine, and  $[8-^3H]$ -guanine<sup>34</sup>-tRNA<sup>Tyr</sup>, respectively. \* 2<sup>nd</sup> substrate:  $[8-^3H]$ -guanine, \*\* taking into account the presence of TGT as a homodimer able to bind only one tRNA molecule at a time [38].

$K_M$  values for preQ<sub>1</sub> could only be determined for the wild-type enzyme and the variants TGT(V<sup>233</sup>G) and TGT(C<sup>158</sup>V). Data from literature [16] are perfectly reproduced for the wild-type enzyme by finding a  $K_M(\text{preQ}_1)$  of

0.9  $\mu\text{M}$ , which approximately corresponds to the  $K_{\text{M}}(\text{guanine})$  value, and a  $k_{\text{cat}}$  twice as high compared to the  $[8\text{-}^3\text{H}]\text{-guanine}$  incorporation. In case of TGT(C<sup>158</sup>V), the  $K_{\text{M}}$  value for preQ<sub>1</sub> increases by a factor of almost 20 with respect to the wild-type TGT, although the Cys<sup>158</sup>Val replacement hardly influences the  $K_{\text{M}}(\text{guanine})$  value. The  $k_{\text{cat}}$  value is slightly decreased by a factor of 3 in comparison to the wild-type enzyme, which is analogously observed in the guanine measurements.  $K_{\text{M}}(\text{preQ}_1)$  for TGT(V<sup>233</sup>G) does not significantly increase. Hence, the Val<sup>233</sup>Gly replacement seemed to have no dramatic influence on substrate affinities. Furthermore, the  $k_{\text{cat}}(\text{preQ}_1)$  value is only slightly decreased by a factor of 3 with respect to the wild-type enzyme.

The reverse ‘washout assay’, where  $[8\text{-}^3\text{H}]\text{-guanine}$  is exorporated from tRNA, implicates a considerably lower signal to noise ratio compared to the basic assay, where the incorporation of  $[8\text{-}^3\text{H}]\text{-guanine}$  into tRNA is monitored. In combination with the dramatically reduced turnover number of the TGT(C<sup>158</sup>V/(A<sup>232</sup>S)/V<sup>233</sup>G) variants, the decrease of radioactivity per time intervall is not sufficient for an accurate determination of Michaelis–Menten parameters. The amount of enzyme used in the assay cannot be further elevated to obtain a better signal, since an excess of substrate has to be assured.

In case of queuine, for the variants TGT(V<sup>233</sup>G), and TGT(A<sup>232</sup>S/V<sup>233</sup>G), only very high queuine concentrations (30 – 500  $\mu\text{M}$ ) lead to a detectable decrease of the radioactive signal due to the exorporation of  $[8\text{-}^3\text{H}]\text{-guanine}$ . However, even at a concentration of 10 mM queuine, the remaining variants TGT(C<sup>158</sup>V), TGT(C<sup>158</sup>V/V<sup>233</sup>G) and TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) are not able to excoporate  $[8\text{-}^3\text{H}]\text{-guanine}$  (Figure 13).

Suprisingly, in the control reaction, for the wild-type enzyme an even faster decrease of the radioactive signal is observed, indicating, that the wild-type enzyme is obviously able to accept queuine as a substrate. In conclusion, all

variants with the Cys<sup>158</sup>Val exchange seem to be unable to excoreporate [8-<sup>3</sup>H]-guanine in the presence of queuine as substrate.

**Figure 13: Excorporation of [8-<sup>3</sup>H]-guanine from labelled tRNA<sup>Tyr</sup> in the presence of queuine.**

#### 4.2.3 Crystal structures

To study the constructed human TGT binding pocket model in structural terms, two variants were crystallised. The TGT(V<sup>233</sup>G) variant, representing the assumed minimal requirement to generate an enlarged binding pocket for queuine accommodation, as well as the TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) variant, representing the binding pocket, probably most similar to the human TGT binding pocket, were selected for this purpose. Besides the uncomplexed proteins, also preQ<sub>1</sub>- and queuine-complexed structures were studied for these variants and will be described in the following.

The superposition of the apo-structures of TGT(V<sup>233</sup>G) and TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) with wild-type TGT (Figure 14a) shows, as expected, that the backbones adopt identical conformations. In addition, there is a dramatic

**Figure 14: Uncomplexed (apo) TGT(V<sup>233</sup>G) and TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) crystal structures.**

**a)** TGT(V<sup>233</sup>G) (blue, 2.25 Å resolution, left), and TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) (red, 1.60 Å resolution, right) apo structures, superimposed with wild-type TGT (green, PDB code 1pud).

**b)**  $2|F_o|-|F_c|$  density contoured at a  $\sigma$  level of 1.5 is coloured blue. TGT(V<sup>233</sup>G) (blue, left), and TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) (red, right) binding pockets, respectively.

gain of space inside the binding pocket due to the amino acid replacements, especially of Val<sup>233</sup>Gly. The generated space is occupied by well-defined water molecules (Figure 14b).

In case of the TGT(V<sup>233</sup>G) variant, the exchanged residue Val<sup>233</sup>Gly is only poorly defined. For the Cys<sup>158</sup> side chain a double conformation is observed. In general, the *B*-factors in the region next to this residue are relatively high in all deposited TGT structures ( $\sim 55 \text{ \AA}^2$ ), compared to other active site residues. In addition, there are two other TGT variant structures, exhibiting a double conformation of the Cys<sup>158</sup> side chain: 1pxg (a Asp<sup>280</sup>Glu variant in complex with preQ<sub>1</sub>, and 1ozq (a Tyr<sup>106</sup>Phe variant in complex with preQ<sub>1</sub>).

**Figure 15: preQ<sub>1</sub> bound TGT(V<sup>233</sup>G) and TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) crystal structures.**

a) TGT(V<sup>233</sup>G) is represented in blue,  $2|F_o|-|F_c|$  density contoured at a  $\sigma$  level of 1.5 is coloured blue,  $|F_o|-|F_c|$  density contoured at  $\sigma$  a level of 3 is coloured green (1.19 Å resolution).

b) TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) is represented in red.  $2|F_o|-|F_c|$  density contoured at a  $\sigma$  level of 1.5 is coloured blue,  $|F_o|-|F_c|$  density contoured at  $\sigma$  a level of 3 is coloured green (1.46 Å resolution).

c) Solvent accessible surface representation of the TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) binding pocket, showing electron densities of the ligand and water molecules.

Nevertheless, in case of the TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) variant, all exchanged residues show well-defined electron density (Figure 14b).

The preQ<sub>1</sub> complex structures of the two variants show, as expected, an analogous binding mode of the ligand (Figure 15). The protein backbone superimposes almost perfectly. However, the high *B*-factors of preQ<sub>1</sub> in the TGT(V<sup>233</sup>G) variant binding pocket indicate, that the ligand is probably not fully occupied. Again, the Gly<sup>233</sup> density is relatively weak and the Cys<sup>158</sup> side chain was refined with a double conformation, although the splitting is only weakly indicated. In case of the TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) variant, all exchanged residues show well defined electron density (Figure 15b). The newly created subpocket is occupied by well-defined water molecules (Figure 15c), most of them at similar positions compared to the apo structures.

In case of queuine, co-crystallised with the TGT(V<sup>233</sup>G) variant, partial density corresponding to the purine heterocycle could be assigned. However, attempts to refine the position of the heterocycle did not reveal conclusive results. Obviously, the ligand shows only minor population or extended disorder in the binding pocket making any refinement of its position unreasonable.

**Figure 16: Crystal structure of TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) co-crystallised with queuine.**

**a)**  $2|F_o|-|F_c|$  density contoured at a  $\sigma$  level of 1.5 is coloured blue,  $|F_o|-|F_c|$  density contoured at  $\sigma$  levels of 3 (left), and 2 (right), respectively, is coloured green (1.60 Å resolution).

**b)** Queuine, docked into the crystal structure with GOLD [39,40]. Two of the highest scored (DrugScore<sup>CSD</sup> [41]) docking poses are shown. Favourable per atom contributions to the overall score are indicated by blue spheres, while the size of the sphere corresponds to the respective contribution, disfavoured per atom contributions are indicated by red spheres.

**c)** Superposition of the two docking poses of queuine with the crystal structure of TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) in complex with queuine.

**d)** Superposition of three active site bound water molecules from the preQ<sub>1</sub>•TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) crystal structure (represented as green spheres) with electron density of the queuine•TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) crystal structure.

In case of the queueine • TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) variant complex structure, the electron density of the purine heterocycle is well defined. For the cyclopentenyl moiety only poorly defined electron density can be observed. Comparing the traces of the electron density and its spacial location with respect to the apo and preQ<sub>1</sub> structures, it appears obvious that the remaining rather large difference electron density peak does not originate from some bound water molecules, present in the apo or preQ<sub>1</sub> structures (Figure 16d). Apparently, the enlarged binding pocket does not offer appropriate interaction partners for the hydroxyl groups of the cyclopentenyl moiety in *H*-bonding distance. Therefore, it is assumed that the ring adopts multiple orientations resulting in a pronounced disorder. Docking queueine into this structure using GOLD [39,40] reveals several binding orientations of the cyclopentenyl ring. None of them establishes strong interactions to the protein (Figure 16b). The two best scored docking solutions overlap in an area that nicely coincides with the observed difference electron density peak. The latter peak could not be assigned to any of the previously detected water molecules in the uncomplexed or preQ<sub>1</sub> bound cases (Figure 16d).

#### 4.2.4 Molecular dynamics simulation

To probe a possible distribution of the cyclopentenyl moiety over several orientations in absence of appropriate interaction partners for directional interactions, molecular dynamics (MD) simulations of the complex were performed. As starting geometry, the TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) variant structure complexed by queueine was used. To generate a reasonable pose for queueine, the ligand was docked into the structure with GOLD [39,40] and minimised with the MAB force field in MOLOC [42]. Analysis of the MD trajectory revealed that, in fact, the cyclopentenyl moiety shows high residual mobility inside the binding pocket (Figure 17a). Two snapshots were extracted from the simulation, and superimposed based on a C<sub>α</sub> fit of all

protein residues with the TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) crystal structure (Figure 17b).

**Figure 17: MD simulation of TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) in complex with queuine.**

- Distance between an atom of the flexible cyclopentenyl moiety and a backbone amide nitrogen from a residue, deep inside the new subpocket, measured over the MD simulation time.
- Two queuine conformers from MD simulation snapshots superimposed with the TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) crystal structure and the electron density.

Very similar to the previously described docking study, the region of the remaining difference electron density that could not be assigned to water molecules, fits nicely with the central part of the cyclopentenyl moiety considering two different orientations of queuine during the MD simulation. These results support the hypothesis that queuine is bound to the TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) variant. *Via* its central part, the obviously highly flexible cyclopentenyl moiety creates the difference electron density of the ligand in this region.

Additionally, also an MD simulation of the uncomplexed wild-type enzyme was performed. Interestingly, also the region between the crucial residues (Val<sup>233</sup>, Cys<sup>158</sup>) exhibits pronounced flexibility (Figure 18). It possibly creates a small subpocket, similar to the one opened in the TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) variant. Moreover, volumes of the different binding pockets were calculated

**Figure 18: MD simulation of apo wild-type TGT.**

Distance between Val<sup>233</sup> C $\alpha$  and Cys<sup>158</sup> S $\gamma$ , measured over the MD simulation time. The green vertical lines indicate snapshots, that have been extracted for the calculations of binding pocket volumes, listed in Table 10.

**Table 10: Binding pocket volumes calculated with CASTp [43].**

TGT	V [10 <sup>2</sup> · Å <sup>3</sup> ]
Wild-type TGT·preQ <sub>1</sub> (1p0e)	2.5
TGT(C <sup>158</sup> V/A <sup>232</sup> S/V <sup>233</sup> G)·queueine	6.5
hTGT homology model	6.0
Wild-type TGT (apo), MD snapshot 1.4 ns	7.5
Wild-type TGT (apo), MD snapshot 2.5 ns	7.1
Wild-type TGT (apo), MD snapshot 3.5 ns	2.5

with CASTp [43] as listed in Table 10. The binding pockets of both, the TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) as well as the hTGT homology model, were found to possess more than twice as large binding pockets, compared to wild-type bacterial TGT. In light of these values it is remarkable to note that the binding pocket volume of the wild-type bacterial TGT can significantly open up as indicated by some frames during the MD simulation due to the mentioned flexibility in the region between the residues Val<sup>233</sup> and Cys<sup>158</sup>. The binding pocket then reaches volumes even larger than the eukaryotic

TGT binding pocket models, large enough for queueine accommodation (Table 10). After several nanoseconds, the original state, where the subpocket is closed again, is adopted, as indicated by the small volume of the binding pocket of the third MD snapshot (Figure 18, Table 10). Therefore, it even might be possible that also the wild-type enzyme is able to bind queueine. Interestingly in this context, wild-type TGT crystals are destroyed under queueine soaking conditions. In case of TGT, such findings often indicate that the soaked ligand is able to bind to the active site but requires structural adaptation of the enzyme destroying crystal contacts. In agreement with this, wild-type TGT was found to be able to excorporate labeled guanine from tRNA in the presence of queueine (Figure 13, p. 79).

#### 4.2.5 Co-crystallisation of the TGT variants with preQ<sub>1</sub> derivatives

To further probe the new, enlarged binding pocket in structural terms, for several preQ<sub>1</sub> derivatives co-crystallisation trials were attempted with the two TGT variants. All selected derivatives, such as a phthalic acid derivative, a dimethylformimide derivative, or a t-butyloxycarbonyl (Boc)-protected preQ<sub>1</sub> (Figure 19), were easily available as intermediates or by-products of the queueine synthesis. These compounds feature spatial requirements which exceed beyond preQ<sub>1</sub>. In contrast, they resemble, in steric terms, more the shape of queueine.

**Figure 19: preQ<sub>1</sub> derivatives.**

**a)** Phthalic acid derivative of preQ<sub>1</sub> **b)** Dimethylformimide derivative of preQ<sub>1</sub>  
**c)** Boc-preQ<sub>1</sub> **d)** Queueine.

Co-crystallisation and soaking attempts of the two TGT variants with the phthalic acid derivative failed. Rather the exposed microseeding or full size crystals were destroyed in the presence of this compound.

Co-crystallisation trials of the two TGT variants with the dimethyl formimide derivative did not yield any bound ligand in the structures.

**Figure 20: Crystal structure of Boc-preQ<sub>1</sub> bound to the TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G).**

**a)**  $2|F_o|-|F_c|$  density contoured at a  $\sigma$  level of 1.5 is coloured blue,  $|F_o|-|F_c|$  density contoured at a  $\sigma$  level of 3 is coloured green (1.26 Å resolution). (1): usual orientation of carbonyl in all other deposited TGT structures, (2): usual position of the following residue 233. **b)** Steric comparison of Boc-preQ<sub>1</sub> with queuine. **c)** Queuine docking pose superposed with the crystal structure of TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) in complex with Boc-preQ<sub>1</sub>.

Interestingly, a complex structure of the TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) variant with Boc-protected preQ<sub>1</sub> could be determined (in the corresponding trial with the TGT(V<sup>233</sup>G) variant only an unoccupied binding pocket could be observed) (Figure 20a). In this complex, the side chain of Ser<sup>232</sup> and the loop Gly<sup>233</sup>–Gly<sup>234</sup> are completely disordered, but the orientation of the Ser<sup>232</sup> carbonyl group indicates already a different conformation of the loop 232–234, compared to all other TGT structures, leading to a probably even larger, and ‘opened’ binding pocket. Volume comparisons of Boc-preQ<sub>1</sub> with queuine reveals good steric similarity (Figure 20b). In addition, the observed Boc-preQ<sub>1</sub> binding conformation superimposes well with the assumed queuine binding modes from docking results (Figure 20c).

In the radioactive ‘washout assay’ the TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) variant is able to excorporate labeled guanine from tRNA in the presence of 10 μM Boc-preQ<sub>1</sub> (chapter 5.3.2f, Appendix). Thus, the enzyme variant seems to be able to not only bind but also accept this preQ<sub>1</sub> derivative as substrate.

## 4.3 Discussion

### 4.3.1 The turnover numbers of the TGT variants decrease dramatically

In this study it was attempted to modify substrate specificity of bacterial TGT towards human TGT to investigate properties of an eukaryotic TGT binding pocket by means of a model system. On the basis of a multiple sequence alignment and homology modelling, three residues were selected for mutation – apart from the Tyr<sup>106</sup>Phe exchange. The TGT variants, however, showed unexpected kinetic behaviour. While  $K_M$  values for guanine and tRNA remained almost unchanged within the experimental error for all variants,  $k_{cat}$  values were reduced by factors of one to two orders of magnitude in several cases.

These results indicate, that although the mutation sites are rather distant from the catalytic residue Asp<sup>280</sup>, they play a crucial role for efficient enzyme turnover rates. As already suggested by Romier *et al.* [11], residues 233 and 158 perform van der Waals interactions to the purine heterocycle of the substrate. They might be important for stabilisation of the complex during catalysis. However, the Cys<sup>158</sup> side chain was observed to be not completely rigid in the TGT(V<sup>233</sup>G) variant crystal structures. A possible explanation could be that upon Gly<sup>233</sup>Val replacement an appropriate bulky partner is missing to fix the orientation of the cysteine side chain. This probably leads to the slight increase of the  $K_M$  value towards preQ<sub>1</sub>.

### 4.3.2 The turnover numbers of TGT variants increase for the substrate base preQ<sub>1</sub>

For preQ<sub>1</sub>  $k_{cat}$  values for the different TGT variants are significantly higher. The enhancement of  $k_{cat}$  for preQ<sub>1</sub> incorporation has already been

discussed [16,37] and possibly correlates with the nucleophilicity of nitrogen *N*9 in the respective substrates. In each case nitrogen *N*9 nucleophilically attacks *C*1 of the covalently bound tRNA ribose<sup>34</sup> during catalysis. In preQ<sub>1</sub>, this nitrogen is the most potent nucleophile, as it is in no electronic conjugation with the exocyclic amino methyl group. In guanine, *N*9 is less nucleophilic due to an electron withdrawing effect of *N*7 being in conjugation with *N*9. This is fully consistent with the observed decrease in turnover in the order preQ<sub>1</sub> > guanine.

### 4.3.3 Increased $K_M$ for preQ<sub>1</sub>

However, the  $K_M$  value for preQ<sub>1</sub> of the TGT(C<sup>158</sup>V) variant is drastically increased (factor 17.5, Table 9). This loss in binding affinity for preQ<sub>1</sub> could be due to different van der Waals contacts provided by Val<sup>158</sup> replacing Cys<sup>158</sup>. Already the  $K_M$  values for guanine show a slight tendency to lower values, upon Cys<sup>158</sup>Val exchange (TGT(C<sup>158</sup>V/V<sup>233</sup>G) and TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) variants, Table 9). Only a few eukaryotic TGTs have been kinetically characterised in literature: from rat liver [8], rabbit erythrocytes [44], and wheat germ [45]. For most of these TGTs no kinetic data concerning preQ<sub>1</sub> were published, except for wheat germ [45], where the authors stated that the affinity of TGT towards preQ<sub>1</sub> was not exactly determined but found to be at least 100-fold reduced in comparison to queueine. Taking into account that eukaryotic TGTs have no physiological need to incorporate preQ<sub>1</sub> into tRNA, as queueine is directly inserted to tRNAs (preQ<sub>1</sub> is not a relevant substrate in eukaryotes), the affinity loss of preQ<sub>1</sub> towards the TGT variants constructed in this study suggests another eukaryotic TGT specific property. Here, the affinity loss observed for the purine heterocycle moiety could possibly be compensated in the actual substrate queueine by additional hydrophobic interactions of Val<sup>158</sup> with the cyclopentenyl moiety. This was already suggested by Romier *et al.* [11]. Furthermore, additional hydrogen bonds could be formed between the hydroxyl groups of the cyclopentenyl moiety

and the protein. This study did not reveal any favourable interaction partners for these hydroxyl groups, and the cyclopentenyl moiety remains disordered in the co-crystal structure. However, a reconsideration of the homology model and the multiple sequence alignment suggests another residue to be exchanged to better approximate human TGT: Tyr<sup>161</sup> (*Z. mobilis* numbering)/Ser<sup>148</sup> (*H. sapiens* numbering). This residue was not considered in the first attempt, since it is quite distant from the substrate binding pocket in the bacterial wild-type TGT binding pocket. It points towards the surface on the back side of the protein. In bacterial TGTs to 75 % tyrosine or phenylalanine is found at this position. In eukaryotic TGTs in 50 % threonine or serine (as in *H. sapiens* TGT) is present, potentially featuring a hydrogen bond towards one of the hydroxyl groups as shown in Figure 21. Queueine was docked into the human TGT homology model using GOLD [39,40] and minimised in the MAB force field of MOLOC [42], leaving only the ligand and the binding sites residues (Asp<sup>89</sup>, Phe<sup>93</sup>, Asp<sup>143</sup>, Val<sup>145</sup>, Ser<sup>148</sup>) flexible. During minimisation, the Ser<sup>148</sup> side chain rotates towards queueine by about 30 °. Also the MD simulation of the complex structure revealed a limited number of interaction sites for the cyclopentenyl moiety of queueine inside the chimeric model binding pocket. Creating an additional interaction site by the Tyr<sup>161</sup>Ser exchange could fix queueine in the binding pocket.

**Figure 21: Queueine docked into the hTGT homology model after minimisation with the MAB force field of MOLOC [42].**

The GOLD [39,40] docking pose was scored with the knowledge-based scoring function DrugScore<sup>CSD</sup>[41]. Favourable per atom contributions are indicated by blue spheres, while the size of the sphere corresponds to the score, disfavoured per atom contributions are indicated by red spheres.

#### 4.3.4 *Z. mobilis* wild-type TGT is eventually able to bind queuine

Surprisingly, in the radioactive ‘washout assay’, the wild-type enzyme showed an excorporation of [8-<sup>3</sup>H]-guanine in the presence of queuine. Okada *et al.* [21] reported that *E. coli* TGT is unable to accept queuine as a substrate. In their assay 50 nM [<sup>14</sup>C]-guanine<sup>34</sup>-tRNA<sup>Tyr</sup> were incubated with 217 nM *E. coli* TGT and 7.5 μM queuine. Already at this concentration, an excorporation of about 10 % of radioactivity is noticeable (Figure 22). In the present study, a concentration of 500 μM led to an even higher amount of radioactivity excorporation (Figure 13, p. 79).

Figure 22: Okada *et al.* [21], Figure 2.

FIG. 2. Release of [<sup>14</sup>C]guanine from [<sup>14</sup>C]guanine-labeled *E. coli* G-tRNA by 7-(aminomethyl)-7-deazaguanine. The reaction mixture contained 0.1 nmol of [<sup>14</sup>C]guanine-labeled *E. coli* G-tRNA<sup>Tyr</sup> (5,000 cpm) and 20 μg of *E. coli* tRNA transglycosylase (Fraction V) with or without 15 nmol of the specified base in 2 ml of 70 mM Tris-HCl (pH 7.5), 20 mM MgCl<sub>2</sub>. Samples of 0.6 ml taken after incubation for 0, 30, and 60 min were chilled and mixed with an equal volume of 30% trichloroacetic acid. The precipitate formed was collected on a glass fiber filter-paper disc, washed four times with cold 5% trichloroacetic acid and dried, and its radioactivity was counted in a liquid scintillation counter.

However, these indirect assays only show that the presence of queuine leads to the excorporation of labeled guanine from tRNA. Thus, it is only cautiously assumed but not proven that it is queuine that is incorporated into tRNA in exchange. In this study, also MALDI-TOF/MS analyses of a RNA oligo<sup>Asp</sup> product of the TGT catalysed reaction were performed. The aim was to record

the base incorporated into tRNA by the enzyme. The results are listed in chapter 4.5 but will not be discussed here, since they did not allow a conclusive interpretation free of any contradictions.

Nevertheless, binding of queuine to wild-type *Z. mobilis* TGT seems not to be impossible: wild-type TGT crystals soaked with queuine immediately dissolved, possibly indicating a binding of queuine to the enzyme. In addition, MD simulations of the wild-type apo structure revealed a flexibility of the region around residues 158 and 233, possibly enabling a binding of queuine between these residues (Figure 18, Table 10, p. 86). Finally, the radioactive ‘washout assay’ clearly showed excorporation of [8-<sup>3</sup>H]-guanine in the presence of queuine.

### 4.3.5 Outlook

In the future, a new crystallisation screen for the wild-type TGT in complex with queuine should be performed to determine the complex structure, or to reveal, what kind of compound is bound to the enzyme.

The variant crystals could be soaked with the cyclopentenyl moiety or other small molecule fragments in addition to preQ<sub>1</sub>, to assess, whether they are able to bind to the generated subpocket. The variants are only models of a eukaryotic TGT binding pocket and possibly do not provide the cyclopentenyl moiety's interaction partners in appropriate distances. Eventually, in a free (not preQ<sub>1</sub>-associated form), the cyclopentenyl moiety is able to adopt a better orientation leading to a better interaction pattern towards the binding pocket of the models. Finally, even though enzymatic characterisation of the variants has been proven difficult or even impossible, structural analysis of an additional Tyr<sup>161</sup>Ser variant could be performed, to further probe the binding pocket of the model system. However, it has to be considered, that amino acid residues further remote from the active site might affect indirectly active site residues as previously reported for TGT [16]. This might provide a slightly different but significantly better interaction pattern towards the queuine cyclopentenyl moiety actually given within an eukaryotic TGT binding pocket.

In conclusion, this study emphasises the importance to characterise the original protein structure to evaluate substrate specificity. Even for quite similar proteins, the composition of the active site, including remote residues taking indirect impact can be different enough to modulate enzymatic activity or specificity. There is still much to be learnt about TGTs originating from different domains of life that cannot be gleaned from homology models.

## 4.4 Summary

tRNA–guanine transglycosylases (TGT) – present in all three domains of life – catalyse a base exchange reaction in tRNAs. In bacteria, the mechanistic pathway of the guanine exchange towards the modified base preQ<sub>1</sub> is well characterised due to crystal structure analyses and elaborate kinetic studies of *Zymomonas mobilis* TGT [11–16]. As TGT plays a key role in pathogenicity of *Shigella flexneri* [26], the causative agent of bacterial dysentery, it has been established as a target for structure–based drug design [30]. However, eukaryotes also possess a TGT with high homology to the bacterial one and most residues inside the binding pocket are conserved [25]. In an analogous reaction the base queueine is incorporated into tRNA. Hence, it is of utmost importance to study selectivity–determining features.

Since no crystal structure of an eukaryotic TGT is yet available, in this study based on *Z. mobilis* TGT a genetically engineered human TGT binding pocket was designed as a model system. Three amino acids specific for the human TGT binding pocket were introduced by site–directed mutagenesis of the *Z. mobilis* TGT gene, (Cys<sup>158</sup>Val, (Ala<sup>232</sup>Ser), Val<sup>233</sup>Gly). After purification, kinetic measurements and crystallisation were performed. Modified assays showed that – surprisingly – the *Z. mobilis* TGT variants have dramatically slowed down so that kinetic parameters could not be determined for incorporation of queueine into tRNA. Nevertheless, crystal structure analysis and molecular dynamics simulations indicate a possible binding of queueine to the active site of the variants. Additionally, it was observed that the wild–type enzyme is able to excorporate labeled guanine from tRNA in the presence of queueine. MD simulations indicate that the enzyme is able to open up a subpocket that potentially could accommodate queueine.

## 4.5 Supplement

### 4.5.1 MALDI-TOF/MS analysis of the RNA product

To record the base incorporated into tRNA by the TGT variants and the wild-type enzyme, another assay was performed. In this assay the RNA product of the reaction was subsequently analysed *via* Matrix-assisted laser desorption/ionisation time-of-flight mass spectrometry (MALDI-TOF/MS). However, highly charged full length tRNA is not applicable for an accurate MALDI-TOF/MS analysis, and secondly, the relative mass difference between native and modified tRNA would be too small (Table 11). It is reported that TGT also

Table 11: Relative mass differences of native and modified RNA substrates.

RNA	mass [Da]	$\Delta$ mass [%]
native oligo <sup>Asp</sup>	6678	
preQ <sub>1</sub> -oligo <sup>Asp</sup>	6707	0.43 %
queueine-oligo <sup>Asp</sup>	6805	1.90 %
native tRNA <sup>Tyr</sup>	27492	
preQ <sub>1</sub> -tRNA <sup>Tyr</sup>	27521	0.11 %
queueine-tRNA <sup>Tyr</sup>	27619	0.46 %

Figure 23: MALDI-TOF/MS analysis of native and preQ<sub>1</sub>-modified RNA oligo<sup>Asp</sup>.

a) Sequence and assumed mini-helix structure of the tRNA<sup>Asp</sup> anticodon stemloop RNA oligo, b) MALDI-TOF mass spectrum of unmodified RNA oligo<sup>Asp</sup>, c) MALDI-TOF mass spectrum of preQ<sub>1</sub>-modified RNA oligo<sup>Asp</sup> ( $\Delta$ mass to (b): 29 Da).

accepts so-called ‘mini-helices’ [18] as RNA-substrate. Thus, a 21mer RNA oligo (corresponding to the tRNA<sup>Asp</sup> anticodon stemloop) was purchased (Figure 23a). First control experiments with the wild-type enzyme and 500  $\mu$ M preQ<sub>1</sub> showed that, in fact, the RNA oligo<sup>Asp</sup> is accepted as substrate and preQ<sub>1</sub> is incorporated. This is indicated as native and preQ<sub>1</sub>-modified RNA oligo<sup>Asp</sup> could be clearly distinguished in the MALDI-TOF mass spectra. The observed mass difference corresponds to the expected values (Figure 23b, c; Table 12). Also lower preQ<sub>1</sub> concentrations were tested. Already a concentration of 5  $\mu$ M lead to a detectable, but only partial guanine to preQ<sub>1</sub> replacement, while at a concentration of 1  $\mu$ M only unmodified RNA oligo<sup>Asp</sup> can be detected.

**Table 12: MALDI-TOF/MS analysis of RNA oligo<sup>Asp</sup> reaction products.**

<b>TGT</b>	<b>substrate</b>	<b><math>\Delta</math>mass<sup>1</sup> [Da]</b>
<b>wild-type TGT</b>	preQ <sub>1</sub>	29 $\pm$ 2
<b>TGT(V<sup>233</sup>G)</b>	preQ <sub>1</sub>	28 $\pm$ 2
<b>TGT(C<sup>158</sup>V/V<sup>233</sup>G)</b>	preQ <sub>1</sub>	28 $\pm$ 2 <sup>(2)</sup>
<b>wild-type TGT</b>	queuine	27 $\pm$ 2 <sup>(2)</sup>
<b>TGT(V<sup>233</sup>G)</b>	queuine	27 $\pm$ 2 <sup>(2)</sup>
<b>TGT(C<sup>158</sup>V)</b>	queuine	–
<b>TGT(C<sup>158</sup>V/V<sup>233</sup>G)</b>	queuine	–
<b>TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G)</b>	queuine	–
<b>wild-type TGT</b>	Boc-preQ <sub>1</sub>	38 $\pm$ 2 <sup>(2)</sup>
<b>TGT(V<sup>233</sup>G)</b>	Boc-preQ <sub>1</sub>	38 $\pm$ 2 <sup>(2)</sup>
<b>TGT(C<sup>158</sup>V)</b>	Boc-preQ <sub>1</sub>	38 $\pm$ 2 <sup>(2)</sup>
<b>TGT(C<sup>158</sup>V/V<sup>233</sup>G)</b>	Boc-preQ <sub>1</sub>	38 $\pm$ 2 <sup>(2)</sup>
<b>TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G)</b>	Boc-preQ <sub>1</sub>	38 $\pm$ 2 <sup>(2)</sup>

1) Mass differences to native oligo (6678 Da): 29 Da would correspond to a preQ<sub>1</sub> modification of the RNA oligo<sup>Asp</sup>, 127 Da to a queuine modification, 128 Da to a Boc-preQ<sub>1</sub> modification, 2) Only partial modification observed.

Also the TGT(V<sup>233</sup>G) variant (decreased  $k_{\text{cat}}$  by a factor of about 3 – 10 with respect to the wild-type TGT values, Table 9, p. 77) is able to incorporate preQ<sub>1</sub> efficiently (Table 12), once incubated with 500  $\mu$ M preQ<sub>1</sub>. It can be assumed, that the TGT(C<sup>158</sup>V) variant (decreased  $k_{\text{cat}}$  by a factors of about 3

with respect to the wild-type TGT values, Table 9, p. 77) is able to incorporate preQ<sub>1</sub> with similar efficiency, since the (irreversible) exchange reaction has been executed for more than 16 h. For such a long time span even the increased  $K_M(\text{preQ}_1)$  value should not matter significantly. The TGT(C<sup>158</sup>V/V<sup>233</sup>G) variant (decreased  $k_{\text{cat}}$  by a factor of about two orders of magnitude with respect to the wild-type TGT values, Table 9, p. 77) is found to be rather inefficient, thus only a reduced quantity of preQ<sub>1</sub> modification is detected besides unmodified RNA oligo<sup>Asp</sup>. In light of this finding it can be assumed, that also the TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) variant with a similarly reduced  $k_{\text{cat}}$  (Table 9, p. 77) is only capable to produce minor amounts of preQ<sub>1</sub>-modified RNA oligo<sup>Asp</sup>.

**Figure 24: MALDI-TOF/MS analysis of RNA oligo<sup>Asp</sup> reaction products upon incubation with queueine.**

**a)** MALDI-TOF mass spectrum of partially preQ<sub>1</sub>-modified RNA oligo<sup>Asp</sup>, produced by wild-type TGT incubated with queueine, **b)** MALDI-TOF mass spectrum of native (unmodified) RNA oligo<sup>Asp</sup>, produced by TGT(C<sup>158</sup>V) incubated with queueine.

Incubation of the RNA oligo<sup>Asp</sup> with 500  $\mu\text{M}$  pure queueine, results in no significant queueine modification. In case of TGT(C<sup>158</sup>V), TGT(C<sup>158</sup>V/V<sup>233</sup>G), TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) only unmodified RNA oligo<sup>Asp</sup> could be isolated (Figure 24b). These results are in good agreement with the radioactive ‘washout assay’, where these three variants were found to be not sufficiently active to produce a measurable signal. However, in case of the remaining TGT(V<sup>233</sup>G) variant and the wild-type enzyme, the mass spectra showed

surprising results. A signal with a mass difference is observed, that suggests incorporation of preQ<sub>1</sub> (Figure 24a; Table 12, p. 98). Contamination of queuine by preQ<sub>1</sub> can be excluded as high pressure liquid chromatography coupled with electrospray ionisation mass spectrometry<sup>1</sup> (HPLC/ESI-MS) and <sup>1</sup>H-NMR spectrum<sup>2</sup> analyses did not provide any evidence. In addition, since the radioactive ‘washout assay’ suggested also Boc-preQ<sub>1</sub> as a substrate, RNA oligo<sup>Asp</sup> products of the corresponding reaction were analysed as well (chapter 5.4.j–m, Appendix). The detected peaks do not correspond to any expected masses. Rather, it is awkward to interpret the calculated mass differences (Table 12, p. 98). Thus, MALDI-TOF/MS analysis of the RNA product seems to be not appropriate to determine the base that had been incorporated by TGT.

#### 4.5.2 MALDI-TOF/MS assay drawbacks

MALDI-TOF/MS analysis of the RNA oligo<sup>Asp</sup> products obtained after incubation with the TGT variants was only successful for those variants, that exhibited an only moderately decreased reaction velocity. Due to the temperature sensitivity of the RNA oligo<sup>Asp</sup> substrate, the reaction mixture was incubated at 25 °C. To compensate for the probably lower enzymatic activity at this temperature, incubation time was elongated to 16 h (in comparison, the [8-<sup>3</sup>H]-guanine assay which is performed at 37 °C was only elongated from 4 min to 30 min to receive a measurable signal of the variants). Yet, there are additional difficulties. Curnow *et al.* [18] reported a 6-fold increase of  $K_M$  for a 17-base tRNA<sup>Tyr</sup> anticodon stemloop. For wild-type TGT only a rough estimation of the  $K_M$  value for the RNA oligo<sup>Asp</sup> substrate could be performed *via* Lineweaver-Burk linear regression of [8-<sup>3</sup>H]-guanine assay data (chapter 5.3.1f, Appendix). Already for the wild-

---

<sup>1</sup>) Performed by Anja Vogt, Institut für Pharmazeutische Chemie, Philipps-Universität Marburg.

<sup>2</sup>) Performed by Hans-Dieter Gerber, Institut für Pharmazeutische Chemie, Philipps-Universität Marburg.

type enzyme, the approximate  $K_M$  with 1.5 mM is quite high. For the even less active variants, assuming no further increase of the  $K_M$ , the catalytic efficiency would be by far too low to record detectable modification of the RNA oligo<sup>Asp</sup>. Curnow *et al.* [18] reported that a 4-base elongation of their minihelix led to a stemloop that is stable at 37 °C. This could be a possibility to increase the performance of the less active variants, eventually leading to a detectable modification of the RNA oligo<sup>Asp</sup>. Nevertheless, the conditions applied during MALDI-TOF/MS analysis of the RNA oligo<sup>Asp</sup> have to be examined first. The results described above cannot be interpreted consistently but they might indicate that the stability of the base modification is not sufficient to survive the applied conditions in the MALDI-TOF/MS experiments.

In literature, analysis of tRNA<sup>Tyr</sup> RNase T<sub>1</sub> hydrolysis by PEI-cellulose chromatography had revealed the position of modification in tRNA [21], and tRNA modification with CNBr and RPC-5 analysis could distinguish between native and queueine modified tRNAs [46–48]. These techniques could possibly support the analysis of full length tRNA after incubation with the TGT variants.

## 4.6 Materials and Methods

### 4.6.1 Homolgy modelling

Amino acid sequences were extracted from the deposited crystal structures with PDB codes: 1r5y (chain A), 1y5v (chain A), 1y5w (chain A), 1ozm (chain A), 1ozq (chain A), and 1q2r (chain A, and B, respectively). These sequences were aligned with the human TGT sequence (from SWISS-PROT Release 54.3 [49]) utilising Clustal W 1.83 [33]. The sequences aligned with 41 –42 % identity. Based on the alignment, ten homology models for human TGT were calculated with MODELLER 6a [35]. The best model (model no. 8) was selected by picking the model with the lowest value (11,429.19) of the MODELLER objective function, which is reported in the second line of the model PDB file.

### 4.6.2 Construction of the TGT mutants C158V, V233G, C158V–V233G, A232S–V233G, C158V–A232S–V233G

Site-directed mutagenesis was performed using the QuickChange™ kit (Stratagene) following the vendor's protocol. The oligonucleotides listed in Table 13 were used to introduce the mutations into the Y106F mutant of the *tgt* gene on the expression plasmid pET9d-ZM-Y106F [14]. Sequencing of the entire *tgt* gene (MWG Biotech, Ebersberg) confirmed the presence of the desired mutations as well as the absence of any further unwanted mutation. Subsequently, the mutated plasmids were transformed into *E. coli* BL21 (DE3) pLysS cells.

Table 13: Oligonucleotides used in mutagenesis.

mutation site/ oligo name	sequence (5' to 3') <sup>1</sup>

<sup>1</sup>) The mutated bases are printed in bold letters and highlighted with grey background.

#### 4.6.3 Expression, Purification

*Z. mobilis* TGT variants were prepared as described elsewhere [12,36]. *E. coli* tRNA<sup>Tyr</sup> (ECY2) was prepared as described by Curnow *et al.* [50]. Radio-labeling of tRNA<sup>Tyr</sup> was performed as already described [16].

#### 4.6.4 Determination of kinetic parameters

Kinetic parameters for the TGT variants were determined for the different substrates essentially as described by Meyer *et al.* [51]. Michaelis–Menten parameters for tRNA and guanine were determined monitoring incorporation of radioactively labelled guanine into tRNA<sup>Tyr</sup> in position 34. Kinetic data for both substrates were determined separately in duplicate and average values were calculated. Kinetic parameters for guanine were measured using 150 nM (wild-type, TGT(V233G), TGT(C158V), TGT(A232S/V233G) variants) – 300 nM (TGT(C158V/V233G), TGT(C158V/A232S/V233G) variants) TGT, 15 µM unlabelled *E. coli* tRNA<sup>Tyr</sup>, and variable concentrations of [8-<sup>3</sup>H]-guanine (0.9 Ci/mmol, Hartmann Analytic) in the range of 0.5 – 20 µM in buffer solution (200 mM HEPES pH 7.3, 20 mM MgCl<sub>2</sub>, 0.036 % (v/v) Tween 20 (Roth)). Kinetic parameters for tRNA were measured using 150 nM (wild-type,

TGT(V<sup>233</sup>G), TGT(C<sup>158</sup>V), TGT(A<sup>232</sup>S/V<sup>233</sup>G) variants) – 300 nM (TGT(C<sup>158</sup>V/V<sup>233</sup>G), TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) variants) TGT, 20  $\mu$ M [8-<sup>3</sup>H]-guanine, and variable concentrations of tRNA<sup>Tyr</sup> (0.25 – 15  $\mu$ M). Initial velocities of the base exchange reaction in counts per minute were converted to [ $\mu$ M/min] using a calibration constant derived from liquid scintillation counting of [8-<sup>3</sup>H]-guanine solutions with variable concentrations. Kinetic parameters were determined *via* regression using GraFit [52].

Michaelis–Menten parameters for preQ<sub>1</sub> were calculated *via* monitoring the loss of [8-<sup>3</sup>H]-guanine from tRNA<sup>Tyr</sup> radio-labelled in position 34. Kinetic parameters for preQ<sub>1</sub> were measured using using 150 nM (wild-type, TGT(V<sup>233</sup>G), TGT(C<sup>158</sup>V), TGT(A<sup>232</sup>S/V<sup>233</sup>G) variants) – 300 nM (TGT(C<sup>158</sup>V/V<sup>233</sup>G), TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) variants) TGT and 8  $\mu$ M radio-labelled tRNA<sup>Tyr</sup>. The concentration of preQ<sub>1</sub> was varied in ranges of 0.5 – 15  $\mu$ M, 1 – 50  $\mu$ M, and 25 – 750  $\mu$ M, respectively. Initial velocities in counts per minute were calculated from the decreasing tritium labelling level of tRNA due to the incorporation of the respective substrate bases. Initial velocities in counts per minute were converted to [ $\mu$ M/min] using a calibration constant derived from liquid scintillation counting of guanine/ [8-<sup>3</sup>H]-guanine solutions with variable concentrations. Kinetic parameters were determined *via* regression using GraFit [52].

#### 4.6.5 MALDI–TOF/MS analysis

342 pmol of the RNA oligo<sup>Asp</sup> were incubated with 1.78  $\mu$ M TGT, 1 – 500  $\mu$ M preQ<sub>1</sub> or queuine in 200 mM HEPES, pH 7.3, 20 mM MgCl<sub>2</sub> at 25 °C for at least 16 h. TGT and free preQ<sub>1</sub> or queuine were extracted from the reaction mixture by the addition of equal volumes of Roti–Phenol (Roth) and chloroform : isoamylalcohol (24:1). The aqueous supernatant was once more treated with an equal volume of chloroform : isoamylalcohol (24:1). An additional purification step was performed *via* gel filtration using NAP–

columns (GE Healthcare, Life Science). The RNA oligo was eluted with pure nuclease-free water and vacuum dried. The samples were further purified utilising magnetic beads and analysed by MALDI-TOF/MS by Dr. Silke Seeber and Nico Vogel (Institut für Biochemie, Friedrich-Alexander-Universität Erlangen-Nürnberg).

#### **4.6.6 Crystallisation, data collection, and processing**

Recombinant *Z. mobilis* TGT was expressed in *E. coli* BL21 (DE3), purified and crystallised as described previously [12,36]. TGT variant crystals suitable for ligand soaking were produced in a two step procedure. Droplets were prepared by mixing 2 µl of concentrated protein solution (14 mg/ml) with 2 µl reservoir solution [100 mM Tris/HCl, pH 8.5, 1 mM DTT, 13 % (w/v) PEG 8,000, 10 % (v/v) DMSO]. Micro-crystals were grown at 291 K using the hanging-drop vapour diffusion method in the presence of 1.0 ml of reservoir solution of the respective seeding buffer. Micro crystals grew within two weeks.

Subsequently, macro-seeding was performed under similar conditions to obtain crystals of the uncomplexed protein. Again droplets were prepared by mixing 2 µl of concentrated protein solution with 2 µl macro-seeding reservoir solution [100 mM Tris/HCl, pH 8.5, 1 mM DTT, 5 % (w/v) PEG 8,000, 10 % (v/v) DMSO]. One micro-crystal was transferred into this solution. Single crystals with a size of approximately 0.7 x 0.7 x 0.2 mm<sup>3</sup> grew within two to four weeks.

To allow co-crystallisation of the TGT variants in complex with queueine the compound was dissolved in DMSO and added to the macro-seeding droplet to a final concentration of 1 to 20 mM. Crystals of the TGT variants complexed to preQ<sub>1</sub> were produced by a soaking procedure. The compound was dissolved in DMSO and added to 2 µl of a crystallisation droplet to a final

concentration of 10 to 20 mM. Finally, a single TGT crystal was transferred into the droplet and soaked for 30 min.

For data collection, crystals were cryoprotected using glycerol. The glycerol and PEG 8,000 concentrations of the macro-seeding buffers were increased stepwise by transferring the crystals to six different 2  $\mu$ l cryo-droplets each with 5 to 30 min incubation times [glycerol concentrations (v/v): 5 %  $\rightarrow$  10 %  $\rightarrow$  15 %  $\rightarrow$  20 %  $\rightarrow$  25 %  $\rightarrow$  30 %; and PEG 8,000 concentrations (w/v): 5.0 %  $\rightarrow$  6.3 %  $\rightarrow$  7.5 %  $\rightarrow$  8.0 %  $\rightarrow$  8.8 %  $\rightarrow$  9.8 %, respectively]. These droplets also contained the ligands at equivalent concentrations compared to soaking and co-crystallisation conditions. The cryo-soaked crystals were flash-frozen in liquid N<sub>2</sub>. Data sets were collected at cryo conditions (100 K) at the BESSY (Berliner Elektronenspeicherring-Gesellschaft für Synchrotronstrahlung, Berlin, Germany), PSF (Proteinstrukturfabrik) beamline BL-14.2 and with CuK $\alpha$  radiation ( $\lambda = 1.5418$  Å) using a Rigaku RU-300 rotating-anode generator at 50 kV and 90 mA equipped with Xenocs focussing optics and an R-Axis IV detector. All crystals tested exhibited monoclinic symmetry in space group C2 containing one monomer per asymmetric unit with Matthews coefficients of 2.3 – 2.4. Data processing and scaling was performed using the HKL2000 package [53]. For all refined structures unit cell dimensions for the crystals, data collection and processing statistics are given in Table 14.

Coordinates of the apo TGT crystal structure grown at pH 8.5 (PDB-code: 1pud) were slightly modified (deletion of coordinates at the mutation sites) before applying for initial rigid-body refinement of the protein molecule followed by repeated cycles of conjugate gradient energy minimisation, simulated annealing and B-factor refinement using the CNS program package [54]. Refinement at the later stages for all structures was performed with SHELXL [55]. Here, up to 50 cycles of conjugate gradient minimisation were performed with default restraints on bonding geometry and B-values: 5 % of all data were used for  $R_{\text{free}}$  calculation. Amino acid side chains were fit to  $\sigma$ A-weighted  $2|F_o| - |F_c|$  and  $|F_o| - |F_c|$  electron density maps using

Coot [56]. Water, glycerol molecules, and ligands were located in the difference electron density and added to the model for further refinement cycles. Anisotropic conjugate gradient refinement resulted in a significant improvement of the models built for 2nso, 2nqz, 3bld, 3bll. During the last refinement cycles, riding H-atoms were introduced for the protein residues (not for the ligand) without using additional parameters. All final models were validated using PROCHECK [57]. Data refinement statistics are given in Table 14.

**Table 14: Crystallographic table.**

- a)* number in parentheses is for highest resolution shell
- b)*  $R(I)_{sym} = \Sigma |I - \langle I \rangle| / \Sigma I$  with  $I$  representing the observed intensities and  $\langle I \rangle$  representing the mean observed intensity
- c)*  $R_{work} = \Sigma_{hkl} |F_o - F_c| / \Sigma_{hkl} |F_o|$ .
- d)*  $R_{free}$  was calculated as for  $R_{work}$  but on 5 % of the data excluded from the refinement.

#### 4.6.7 Molecular Dynamics Simulation

The MD simulation and all setup steps were performed with the Amber 8.0 suite of programs using the Amber 1999 force field [58]. The TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G) variant queueine complex structure was used as starting coordinates. The ligand and all crystallographic water molecules were removed. Queueine was docked into the structure using GOLD [39,40] and minimised in the MAB force field of MOLOC [42], defining only the queueine atoms as flexible, while protein atoms were left rigid. For the apo wild-type structure simulation, 1pud was used. Missing residues and side chains were added and minimised with the Amber 1999 force field. After estimating protonation states of all histidines by visual inspection of interactions, histidines were set to the appropriate form (double protonated: 'HIP' / protonated at N $\delta$ : 'HID' (HIS#: 73, 257, 319, 332, 333) / protonated at N $\epsilon$ : 'HIE' (HIS#: 90, 127, 133, 145, 349)). Cysteins coordinating the Zn<sup>2+</sup> ion were set to 'CYM' (CYS#: 319, 320, 323). Hydrogen atoms were added with PROTONATE. The protein was initially subjected to 200 steps of minimisation using a generalised Born solvation model. Subsequently, the systems were solvated in a box of 2563 (TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G)·queueine complex) / 2350 (apo wild-type TGT) TIP3P water molecules [59], and two (TGT(C<sup>158</sup>V/A<sup>232</sup>S/V<sup>233</sup>G)·queueine complex) / three (apo wild-type TGT) sodium ions were added to ensure neutrality. After 200 steps of minimisation of the solvated systems, the MD simulations were started by heating the solvent to 300 K over a period of 20 ps and cooling to 100 K over 5 ps, keeping the protein fixed. Then the entire system was brought to 300 K over a period of 25 ps and the simulation was carried on for 5 ns under NPT conditions, using a time step of 2 fs and PME [60] for evaluating the electrostatic interactions. Energy data were saved every 20 fs, protein coordinates every 0.5 ps. CARNAL was used for further analysis of the trajectory and VMD 1.8.2 [61] for visualisation.

#### **4.6.8 Alignment and Figures**

Alignment of structures with similar or identical sequences was performed with the alignment function implemented in Pymol (<http://www.pymol.org>). Figures were prepared using Isis Draw (MDL, San Leandro, USA) and Pymol.

#### **4.6.9 Protein Data Bank Accession Codes**

The following Protein Data Bank (PDB) accession codes were allocated to the crystal structures determined during this work: 2nso, 2nqz, 3bl3, 3bld, 3bli, 3blo (also given in Table 14).

#### **4.7 Acknowledgements**

This work was supported by the NIH (Grant GM065489) and by the Deutsche Forschungsgemeinschaft (Graduiertenkolleg “Protein Function at the Atomic Level”). We gratefully acknowledge the BESSY (Berliner Elektronenspeicher-ring-Gesellschaft für Synchrotronstrahlung) in Berlin, Germany, for providing beamtime at the PSF (Proteinstrukturfabrik) beamline BL-14.2. We thank Christian Sohn for his support during X-ray data collection, Claudia Sass for performing magnetic beads purification of the RNA oligo samples, Hans-Dieter Gerber for synthesising preQ<sub>1</sub> and queuine and Andreas Blum for helpful discussions.

## 5 Appendix

### 5.1 X-ray refinement Toolkit – Manual

This toolkit is a python [1] based script set, written to assist the setup of X-ray refinement cycles. The respective scripts extract all necessary values from log files, subsequently edit input files for the following refinement cycle and start the corresponding refinement programs. Afterwards, the new log files are checked and several values are extracted and written to a summary file (`info.txt`, File 2, p. 122). The script is adjusted to the refinement strategy commonly applied in our group: Data processing should be performed with HKL2000 [2], rigid body refinement and simulated annealing procedures with cns [3], and refinement with either cns or shelxl [4]. Generated electron density maps are converted by the scripts for a direct read into coot [5]. This toolkit is currently available under `/nfs/extern/pub/inhouse/(incoming/) tidten/`.

#### 5.1.1 Arrangement of folders and subfolders

**Figure 25: Folder arrangement required by the toolkit.**

A short README file describes the usage of the toolkit. For proper performance of the toolkit, a certain arrangement of folders and subfolders has to be maintained (Figure 25). Images of the dataset can be stored in any directory. However, the HKL2000 processing log file and reflections file (`scaleui.log`, `output.sca`) have to be available under `dataset/process/`. After having processed the dataset, and thus having generated the folder `dataset/process/`, the script `make_dir.py` can be

applied to generate the folder `dataset/refine/` with its subfolders.

Additionally, the python toolkit files are automatically copied to **dataset/refine/python/**.

**dataset/refine/** contains three subfolders: **cns/** (for rigid body refinement and simulated annealing procedures performed with cns, and cns refinement cycles), **shelxl/** (for shelxl refinement cycles), **info/** (containing the toolkit files in the subfolder **python/** and the summary file (**info.txt**, File 2, p. 122), where important information is entered during the usage of the toolkit).

### 5.1.2 default.txt

Before the toolkit is used, several files have to be prepared. The HKL2000 files (**scaleui.log**, **output.sca**) have to be present in **dataset/process/** as described above. The file **default.txt** (File 1) provided by the toolkit, has to be edited and stored under **dataset/refine/info/**. In **default.txt** names of files, which are read while the script runs, can be changed if desired. The 'short name' of protein and ligand is used to generate the file names of each refinement cycle (*e.g.* **01-prot-lig.ins**).

#### File 1: default.txt

Please change default-file-names here:

CNS:	
pdb-file, coordinates for MR:	start.pdb
sca-file, HKL2000 output:	output.sca
log-file, HKL2000:	scaleui.log
short name of your protein:	prot
short name of your ligand:	lig
SHELXL:	
dfx-file, inserted in shelxl-ins-file:	GOL.dfx
start- and end-aa in refinement-model:	11-383
seq-file, sequence of your whole protein:	prot.seq

### 5.1.3 Ligand restraints (shelxl dfx file)

A shelxl restraint file for glycerol molecules is provided by the toolkit (**GOL.dfx**). For any other ligand molecules, restraints have to be manually generated utilising the shelxpro option [J] and may then be simply appended to the **GOL.dfx** file in **dataset/refine/info/python/**.

### 5.1.4 Protein sequence file

A file containing the (entire) one letter amino acid sequence of the protein has to be present in **dataset/refine/info/**. This file is used to generate additional output files after a shelxl run as described later. Storing the entire protein sequence instead of only the refined residues has the advantage that during PDB deposition of the final structure, the complete sequence is already available.

### 5.1.5 start.pdb

A pdb file containing coordinates for rigid body refinement and simulated annealing procedures performed by cns has to be provided under **dataset/refine/cns/** and named as declared in **default.txt (start.pdb)**.

### 5.1.6 First cns run

Subsequently, structure solution can be started from **dataset/refine/cns/** utilising the script **cns1.py**. This script first requests data collection information, such as date of data collection, detector type, exposure time, detector distance, oscillation range, radiation wavelength. These values have to be declared upon PDB deposition. Thus, correct completion is recommended but not necessary for proper function of the toolkit, except

## File 2: info.txt

#####

the radiation wavelength, which is essentially required and inserted into input files later on. Thereafter, processing data, such as  $R_{\text{sym}}$ ,  $I/\sigma$ , resolution, number of reflections, unit cell, are extracted from HKL2000 files and written to the summary file (**info.txt**, File 2, p. 122) in **dataset/refine/info/**.

Before **cns** runs are started by the script, the corresponding input files (**make\_cv.inp**, **generate.inp**, **rigid.inp**, **refine.inp**) are edited according to the previously extracted information. Additionally, the HKL2000 reflection file **output.sca** is copied to the folder **dataset/refine/cns/** and converted to the **cns** compatible **xpl** format. The log files written by the **cns** runs are read and the script is aborted if errors are found, so that manual adjustment of input files or others (such as **start.pdb**) is possible. The subsequent start of the script **cns1.py** then utilises the manually edited **cns** input file from **dataset/refine/cns/**. **cns** runs are started in the following sequence: **make\_cv**, **generate**, **rigid**, **refine**. After successful **cns** runs, maps generated by the **refine** run are converted to the **coot** compatible **ccp4** format,  $R_{\text{work}}/R_{\text{free}}$  values are extracted from the log file and written to the summary file **info.txt**.

In general, the toolkit script suggests default answers (given in brackets behind the question), which can be applied by pressing the ‘**ENTER**’ key. If a decision has to be made, the answer given in capitals is defined as the default answer (*e.g.* ‘**(y/N)**’ means, if only the ‘**ENTER**’ key is pressed, the adopted answer is ‘**N**’).

### 5.1.7 Second and following **cns** runs

All following **cns** runs should be started by the script **cns2ff.py**. **cns2ff.py** first requests the name of the latest **pdb** file of the previous **coot** refinement and splits this file into separate **pdb** files containing protein atoms, ligand atoms, ions, water molecules, and glycerol molecules (declared as ‘prosthetic

group'), respectively, if present. The cns input files **generate.inp**, **minimize.inp**, **bindividual.inp**, **water\_pick.inp**, **model\_map.inp** are edited and cns runs are started in the following sequence: **generate**, **minimize(1)**, **bindividual**, **water\_pick**, **minimize(2)**, **model\_map** (fofc), **model\_map** (3fo2fc). If a non-protein, non-water, non-glycerol residue is present, the user is asked to decide whether the respective residue should be considered as an ion or as a ligand. In the first case, the standard ion restraints are added to the input files, while in the second case, the user is asked to provide name and path of a restraint file. After successful cns runs, maps are converted to the coot compatible ccp4 format,  $R_{\text{work}}/R_{\text{free}}$  values are extracted from the log file and written to the summary file **info.txt**.

#### 5.1.8 First shelxl run

For high resolution datasets, the **cns2ff.py** script can be skipped, and **shelxl1.py** can be started from **dataset/refine/shelxl/**. This script first copies the last cns refinement pdb file and the reflection file to **dataset/refine/shelxl/** and generates the shelxl input file (**.ins**) as well as the hkl file (reflections, marked for the calculation of  $R_{\text{free}}$ , which were not used during cns refinement are maintained) by utilising shelxpro and a batch file. Subsequently, in a separate shell, the generated ins file may be edited with the shelxpro option **[U]**, *e.g.* for the refinement of double conformation occupancies or the transformation of water molecule coordinates to the nearest symmetry equivalent. Additional command lines may be inserted manually as well. If required, also a new ins file can be generated manually with the shelxpro option **[I]**, but the file name has to be kept consistently. The script is resumed by typing in 'y' ("Have you finished? (y)"). In the next step, the ins file is edited by the script. The number of refinement cycles is changed (**CGLS** line) according to the user input, and '-1' is added automatically to the line for  $R_{\text{free}}$  calculation, 'ANIS' for anisotropic refinement can be inserted, **HFIX** restraints can be switched on, and the **GOL.dfx**

restraints file is inserted. The **HKLF** code is set to 3 (F) per default (since the hkl file is generated from the **cns .cv** file, maintaining the set of reflections used for  $R_{\text{free}}$  calculation) but can be changed to 4 ( $F^2$ ), if required. **HOPE** can be switched on and off as desired and the weighting factor (**WGHT**) can be changed from 0.1 (default value) to 0.2 for final refinement cycles. A **shelxl** run is then started by the script, writing a log file automatically. After a successful **shelxl** run,  $R_{\text{work}}/R_{\text{free}}$  values, as well as the number of refined water, ligand and glycerol molecules are written to the summary file **info.txt**. Additionally, the following files are generated: **01-prot-lig.lig**, **01-prot-lig.ala**, **01-prot-lig.gap**, **01-prot-lig.db1**. The **.lig** file contains all residue names, which are considered as 'ligand' (non-protein, non-water, non-glycerol. Thus, also ions are counted in the respective field of **info.txt** and listed in the **.lig** file). The **.ala** file contains all residue numbers and original names, which are present as alanine in the refinement **pdb** file, but have a different side chain according to the sequence file (**dataset/refine/info/prot.seq**). The **.gap** file contains all missing residues, according to the sequence file, and is used to automatically generate '**HFIX 33**' lines in the next refinement cycle for the *N*-terminal end of the gap, if required. The **.db1** file contains all double conformations and their corresponding refined occupancies. The respective total numbers of residues in gaps, with double conformations, artificial alanines, or ligands are listed as well in the summary file **info.txt**.

For huge datasets, an analogous **shelxh1.py** script is available, starting **shelxh** instead of **shelxl**. Nevertheless, the folder has to be named 'shelxl' anyway. The default answers differ slightly in **shelxh1.py**: **HOPE** is switched off, **HFIX** restraints are switched on and '**ANIS**' is inserted per default. These settings can be changed if desired.

### 5.1.9 Second and following shelxl runs

All following shelxl runs should be started with the script **shelx12ff.py**. This script skips the file copying from cns performed in **shelx11.py**, and instead changes the file name of the already existing hkl file corresponding to the new refinement cycle. In addition, all steps of the script **cleanup\_pdb.py**, which is also separately available (chapter 5.1.11, p. 128), are performed. Chain IDs (generated by coot *e.g.* upon molecule merging or sorting) are deleted, ligands and glycerols are sorted before the water molecules (the coot 'merge molecules' function usually appends glycerols to the end of the pdb file and thus after already refined water molecules). Water molecules suggested by the previous shelxl run exhibit 'w' as atom names, which are not considered by the subsequent shelxpro generated **.ins** file if not changed to 'o'. All water molecules have to be checked during coot refinement and deleted, if required. The remaining 'w'-water molecules will be changed to 'o', and thus be considered and refined in the next cycle. The remaining steps are performed analogously to **shelx11.py**.

It has to be noted, that the pdb file from which the shelxl input file for the subsequent refinement cycles is generated, is always chosen by the user (per default, a pdb file with the ending **-coot-0.pdb** of the previous refinement cycle is selected by the script). Thus, if *e.g.* several variants starting from the same pdb file are tested during refinement, also pdb files from a refinement cycle before the previous one can be selected for continuation. The numbering of the refinement cycles will not be affected, but it is possible to add comments concerning the refinement procedure to the summary file at the right end of the lines, without disturbing the architecture of the tables. Such comments will be kept but not considered by the toolkit.

A respective **shelx2ff.py** script is available as well.

### 5.1.10 Utilising the toolkit after a manual refinement

In addition, there are also two scripts provided, allowing the extraction of data processing and shelx refinement information of a refinement that had been performed manually before, or is even finished (`read_all_infos_of_finished_refinements.py`). A subsequent use of the toolkit is facilitated by `shelx12ff_after_manual_refinement.py`.

First, for the use of `read_all_infos_of_finished_refinements.py`, it has to be assured, that for each `.ins` file `.log` and `.lst` files with corresponding names are available. If not, these `.ins` files have to be renamed (such as `.ins_`). The script will not consider them. Besides, a protein sequence file has to be provided in `dataset/refine/info/` (see also chapter 5.1.4, p. 121). `read_all_infos_of_finished_refinements.py` writes all information to a summary file in `dataset/refine/shelx1/info.txt` as already described above (chapter 5.1.8, p. 124) and `.lig`, `.ala`, `.gap` and `.dbl` files are generated for the corresponding refinement cycles. The sequence of refinement cycles is not obtained from the `.ins` file names but from the date and time on which the files had been generated.

If, subsequently, refinement is continued utilising the toolkit, the summary file has to be copied to `dataset/refine/info/`. Afterwards, the first shelx1 run has to be started with the script `shelx12ff_after_manual_refinement.py`. This script is able to accept pdb files with arbitrary file names. Furthermore, the user can specify the starting number of the subsequent refinement cycle (*e.g.* `06-prot-1ig.ins`), to keep the overall numbering consistent.

All following shelx1 runs should be started with the script `shelx12ff.py` (chapter 5.1.9, p. 126).

### 5.1.11 Additional scripts

- analyze\_pdb.py**
- Counts number of protein atoms (considering atom occupancies of double conformations), water molecules, glycerol atoms and ligand atoms.
  - Calculates mean B-values of protein atoms, water molecules, glycerol atoms and ligand atoms.
  - Values are directly displayed within the shell and can be used for crystallographic tables in publications.
- cleanup\_folder.py**
- Deletes all disc space consuming map files except the newest (fcf files are never deleted).
  - Deletes all intermediate coot-pdb-files (such as **01-prot-log-coot-5.pdb**) except the newest.
  - Deletes all session files and folders generated by coot.
  - gzips all files within the present folder.
- cleanup\_pdb.py**
- Deletes chain IDs within a pdb file generated by coot *e.g.* upon molecule merging or sorting.
  - Sorts ligands and glycerols before water molecules (the coot 'merge molecules' function usually appends glycerols to the end of the pdb file and thus after already refined water molecules).
  - Renames water molecule atom names from 'w' (suggested water molecules by shelxl) to 'o'.
- make\_dir.py**
- Generates the **refine** folder and its subfolders which are required by the toolkit.
  - Copies the toolkit files to **dataset/refine/info/python/**.

### 5.1.12 Template files provided by the toolkit

<b>bindividual.inp</b>	cns input file.
<b>default.txt</b>	see chapter 5.1.2, p. 120.
<b>generate.inp</b>	cns input file.
<b>GOL.dfx</b>	shelx restraint file for glycerol molecules.
<b>info-leer.txt</b>	empty <b>info.txt</b> file, may be edited in the first three lines and stored as <b>dataset/refine/info/info.txt</b> before the first run of the toolkit. In this case inserted values are read in automatically by the script and the user is not asked during the usage of <b>cns1.py</b> (chapter 5.1.6, p. 121).
<b>make_cv.inp</b>	cns input file.
<b>minimize.inp</b>	cns input file.
<b>model_map.inp</b>	cns input file.
<b>refine.inp</b>	cns input file.
<b>rigid.inp</b>	cns input file.
<b>tgt.seq</b>	example file, containing the (entire) one letter amino acid sequence of tRNA guanine transglycosylase (TGT).
<b>water_pick.inp</b>	cns input file.

## 5.2 Multiple Sequence alignments

Amino acid residues are coloured by their properties, according to the Clustal W colour code: **red** – hydrophobic, **blue** – acidic, **magenta** – basic, **green** – hydrophilic. consensus symbols: \* – residue identical in all sequences in the alignment, : – conserved substitutions, . – semi-conserved substitutions.

### 5.2.1 Multiple sequence alignment of human TGT with selected bacterial TGT structures

ClustalW 1.83 [6] multiple sequence alignment of human TGT (hTGT) with selected bacterial TGT structures as template for homology modelling. Three wild-type *Zymomonas mobilis* TGT structures (PDB codes: 1r5y, 1y5v, 1y5w – resolutions: 1.20 Å and 1.58 Å, respectively), two Y106F variant structures (PDB codes: 1ozm, 1ozq – resolutions: 1.95 Å and 1.90 Å, respectively), and one structure of a covalent TGT–tRNA intermediate (PDB code: 1q2r (chain A and B) – resolution: 2.90 Å) were chosen.

## 5.3 Kinetic measurements

### 5.3.1 [8-<sup>3</sup>H]-guanine TGT assay

a) Initial velocities plotted against time, Michaelis Menten curve of Tyr<sup>106</sup>Phe / Val<sup>233</sup>Gly TGT variant for [8-<sup>3</sup>H]-guanine and tRNA<sup>Tyr</sup>.

- b) Initial velocities plotted against time, Michaelis Menten curve of Tyr<sup>106</sup>Phe / Cys<sup>158</sup>Val TGT variant for [8-<sup>3</sup>H]-guanine and tRNA<sup>Tyr</sup>.

- c) Initial velocities plotted against time, Michaelis Menten curve of Tyr<sup>106</sup>Phe / Cys<sup>158</sup>Val /Val<sup>233</sup>Gly TGT variant for [8-<sup>3</sup>H]-guanine and tRNA<sup>Tyr</sup>.

d) Initial velocities plotted against time, Michaelis Menten curve of Tyr<sup>106</sup>Phe / Ala<sup>232</sup>Ser / Val<sup>233</sup>Gly TGT variant for [8-<sup>3</sup>H]-guanine and tRNA<sup>Tyr</sup>.

- e) Initial velocities plotted against time, Michaelis Menten curve of Tyr<sup>106</sup>Phe / Cys<sup>158</sup>Val /Ala<sup>232</sup>Ser /Val<sup>233</sup>Gly TGT variant for [8-<sup>3</sup>H]-guanine and tRNA<sup>Tyr</sup>.

- f) Initial velocities plotted against time, Lineweaver/Burk diagram of wild-type TGT for [8-<sup>3</sup>H]-guanine and RNA oligo<sup>Asp</sup> (tRNA<sup>Asp</sup> anticodon stemloop).

### 5.3.2 [8-<sup>3</sup>H]-guanine-tRNA<sup>Tyr</sup> TGT 'washout assay'

- a) Initial velocities plotted against time, Michaelis Menten curve of wild-type TGT and preQ<sub>1</sub>.

- b) Initial velocities plotted against time, Michaelis Menten curve of Tyr<sup>106</sup>Phe / Val<sup>233</sup>Gly TGT variant and preQ<sub>1</sub>.

- c) Initial velocities plotted against time, Michaelis Menten curve of Tyr<sup>106</sup>Phe / Cys<sup>158</sup>Val TGT variant and preQ<sub>1</sub>.

- d) Initial velocities of Tyr<sup>106</sup>Phe / Cys<sup>158</sup>Val / Val<sup>233</sup>Gly TGT variant and preQ<sub>1</sub> plotted against time.

- e) Initial velocities plotted against time, Michaelis Menten curve of Tyr<sup>106</sup>Phe / Ala<sup>232</sup>Ser / Val<sup>233</sup>Gly TGT variant and preQ<sub>1</sub>.

- f) Excorporation of [8-<sup>3</sup>H]-guanine from labelled tRNA<sup>Tyr</sup> in the presence of queueine and Boc-preQ<sub>1</sub>

## 5.4 MALDI-TOF/MS analysis of RNA oligo<sup>Asp</sup> reaction products

- a) Native 21 mer RNA oligo<sup>Asp</sup>.

**b)** preQ<sub>1</sub>-modified RNA oligo<sup>Asp</sup> (produced by wild-type TGT, and 500  $\mu$ M preQ<sub>1</sub>).

**c)** preQ<sub>1</sub>-modified RNA oligo<sup>Asp</sup> (produced by wild-type TGT, and 5  $\mu$ M preQ<sub>1</sub>).

**d)** preQ<sub>1</sub>-modified RNA oligo<sup>Asp</sup> (produced by wild-type TGT, and 1  $\mu$ M preQ<sub>1</sub>).

**e)** preQ<sub>1</sub>-modified RNA oligo<sup>Asp</sup> (produced by Tyr<sup>106</sup>Phe /Val<sup>233</sup>Gly TGT variant).

**f)** preQ<sub>1</sub>-modified RNA oligo<sup>Asp</sup> (produced by Tyr<sup>106</sup>Phe /Cys<sup>158</sup>Val /Val<sup>233</sup>Gly TGT variant).

**g)** Partially preQ<sub>1</sub>-modified RNA oligo<sup>Asp</sup> (produced by wild-type TGT and queueine).

- h)** Partially preQ<sub>1</sub>-modified RNA oligo<sup>Asp</sup> (produced by Tyr<sup>106</sup>Phe /Val<sup>233</sup>Gly TGT variant and queuine).

- i)** Unmodified RNA oligo<sup>Asp</sup> (produced by Tyr<sup>106</sup>Phe /Cys<sup>158</sup>Val TGT variant and queuine).

- j)** RNA oligo<sup>Asp</sup> (produced by wild-type TGT and Boc-preQ<sub>1</sub>).

- k)** RNA oligo<sup>Asp</sup> (produced by Tyr<sup>106</sup>Phe / Cys<sup>158</sup>Val TGT variant and Boc-preQ<sub>1</sub>).

l) RNA oligo<sup>Asp</sup> (produced by Tyr<sup>106</sup>Phe / Cys<sup>158</sup>Val / Val<sup>233</sup>Gly TGT and Boc-preQ<sub>1</sub>).

m) RNA oligo<sup>Asp</sup> (produced by Tyr<sup>106</sup>Phe / Cys<sup>158</sup>Val / Ala<sup>232</sup>Ser / Val<sup>233</sup>Gly TGT variant and Boc-preQ<sub>1</sub>).

TGT	tRNA guanine transglycosylase
TOF	time of flight
Tris	trishydroxymethylaminomethane
tRNA	transfer RNA
TTS	type III secretion
vinc_hd	Vinculin head domain
vir	virulence

## Zusammenfassung

### Strukturelle Charakterisierung und Mutationsstudie von *Shigella* Pathogenitätsfaktoren

An der Bakterienruhr, verursacht durch *Shigella*-Bakterien, erkranken jährlich 163 Mio. Menschen. Die Erreger dringen in die Colon-Epithelzellen des Wirtes ein, vermehren sich dort und infizieren weitere Epithelzellen. Durch diesen Prozess wird ein Großteil des Epithels zerstört. Die Fähigkeit der *Shigellen* zur Invasion ist auf einem Virulenzplasmid kodiert. Die Expression der sog. Invasin-Gene wird durch den Virulenzfaktor VirF kontrolliert. Die Translation der *virF*-mRNA ist von der Aktivität eines tRNA-modifizierenden Enzyms, der tRNA-Guanin-Transglycosylase (TGT), abhängig. TGT-Defektmutanten von *Shigellen* sind kaum noch in der Lage, Wirtszellen zu penetrieren.

### Klonierung, Expression, Aufreinigung und Kristallisation von Invasinen

Im ersten Teil der Arbeit wurden die Invasingene *ipaA*, *spa15*, *ipgB2*, *ospD1*, *ipgE*, die für den *Shigella*-Invasionsmechanismus an unterschiedlicher Stelle von Bedeutung sind, kloniert und durch *E. coli* in großen Mengen produziert, lagen jedoch im Falle von IpaA, OspD1, IpgB2 unlöslich in Form von Einschlusskörpern („Inclusion Bodies“) vor. In anschließenden Arbeiten sollen die Pathogenitätsfaktoren aus den Einschlusskörpern in eine lösliche Form überführt, weiter aufgereinigt und kristallisiert werden. IpgE wurde als Glutathion-S-Transferase-Fusionsprotein erfolgreich in löslicher Form in *E. coli* überproduziert und mittels Affinitätschromatographie, sowie Größenausschlusschromatographie gereinigt. Die Identität des Proteins wurde mittels Massenspektrometrie verifiziert. Durch ein breit angelegtes Kristallisationsscreening wurden Bedingungen identifiziert, die zur IpgE-Kristallisation geeignet sind. Diese sollen in nachfolgenden Arbeiten für eine röntgenkristallographische Strukturaufklärung von IpgE weiter optimiert werden.

## Mutagenesestudie zur Substrat-Spezifität und -Selektivität der TGT

Im zweiten Teil der Arbeit wurden Mutagenesestudien an einem Target der Wirkstoffentwicklung gegen *Shigella* – der TGT – durchgeführt, um neue Erkenntnisse über Substrat-Spezifität und -Selektivität gewinnen zu können.

Die TGTs, evolutionär sehr alte Enzyme, sind in allen drei Domänen des Lebens vertreten, unterscheiden sich allerdings in ihrer Substrat-Spezifität und -Selektivität. So katalysieren zwar alle drei Varianten eine Austauschreaktion, bei der eine Guaninbase in tRNAs durch eine modifizierte Base ersetzt wird. Die eingefügte modifizierte Base ist jedoch in den drei Domänen verschieden (Archae: preQ<sub>0</sub>; Bakterien: preQ<sub>1</sub>; Eukaryoten: Queuin). Interessanterweise können eukaryotische TGTs *in vitro* auch die beiden Substrate ihrer verwandten TGTs erkennen und in tRNAs inserieren, während ihre archaeaele Variante außer dem eigenen Substrat nur Guanin in der Bindetasche aufnehmen kann. Die bakterielle TGT erkennt zwar ebenfalls das archaeaele Substrat, kann aber das eukaryotische Substrat nicht umsetzen.

Die unterschiedlichen Substratspezifitäten der archaeaellen und bakteriellen TGTs beruhen auf einem Peptidbindungsflip im aktiven Zentrum, der in Bakterien durch den Protonierungszustand von Glutamat<sup>235</sup> kontrolliert wird. Der Peptidflip ändert die Eigenschaften der Bindetasche so, dass entweder Guanin oder preQ<sub>1</sub> gebunden werden kann. Das Konformer, das Guanin erkennt, ist ebenfalls in der Lage, preQ<sub>0</sub> zu binden. In Archaea kann die entsprechende Peptidbindung ihre Orientierung nicht ändern, da sie durch eine invariante Rückgratwechselwirkung stabilisiert wird. Für eine TGT(Glu<sup>235</sup> Gln)-Variante, die, ähnlich dem archaeaellen Enzym, eine bevorzugte Stabilisierung des Peptipflips in derjenigen Orientierung gewährleisten sollte, die das Binden von Guanin und preQ<sub>0</sub> bevorzugt, konnte gezeigt werden, dass die Selektivität zugunsten von preQ<sub>0</sub> umgekehrt wird. Zahlreiche Kristallstrukturen der mutierten TGT in Komplex mit den verschiedenen Substraten konnten belegen, dass die Bindetasche im mutierten Enzym tatsächlich hauptsächlich in der Konformation vorliegt, die das Binden von Guanin und preQ<sub>0</sub> ermöglicht.

Die Substrat-Promiskuität des eukaryotischen Enzyms basiert auf der Tatsache, dass die Substratbindetasche sehr groß sein muss, um Queuin aufnehmen zu können. Die entscheidenden Interaktionen werden jedoch zu dem heterozyklischen, guaninähnlichen Teil des Moleküls ausgebildet, der in allen drei Substraten analog ist. So können auch die wesentlich kleineren, aber in diesem Bereich sehr ähnlichen Substrate preQ<sub>0</sub> und preQ<sub>1</sub> durch die eukaryotische TGT erkannt und umgesetzt werden. Im Vergleich eines Homologiemodells der humanen TGT mit einer Kristallstruktur der *Zymomonas mobilis* TGT wurden Aminosäuren in der Bindetasche identifiziert, die für eine Vergrößerung der Bindetasche in eukaryotischen TGTs verantwortlich sein könnten. Um die Unterschiede der bakteriellen und humanen TGT-Bindetaschen näher zu beleuchten, wurden *Z. mobilis* TGT-Varianten konstruiert, bei denen diese Reste ausgetauscht wurden, um eine solch vergrößerte Bindetasche zu schaffen, und biochemisch sowie strukturell charakterisiert. Die erzeugten TGT-Varianten zeigten eine signifikante Erniedrigung ihrer Wechselzahlen. Es muss daher angenommen werden, dass die ausgetauschten Reste, trotz ihrer relativ großen Entfernung zum katalytischen Rest Asp<sup>280</sup>, einen entscheidenden Einfluss auf die katalytische Aktivität des Enzyms ausüben. In kinetischen Messungen wurde beobachtet, dass lediglich eine der TGT-Varianten TGT(Val<sup>233</sup>Gly), sowie unerwarteter Weise bereits das *Z. mobilis* Wildtyp-Enzym bei sehr hohen Queuin-Konzentrationen in der Lage sind, radioaktiv markiertes Guanin aus tRNA in Gegenwart von Queuin auszubauen. Analyse von Komplex-Kristallstrukturen und Molekular-Dynamik-Simulationen unterstützen diese Ergebnisse.

## Danksagungen

Bei Herrn Prof. Dr. *GERHARD KLEBE* möchte ich mich für das interessante Thema, seine stete Diskussionsbereitschaft, seine großzügige Förderung zahlreicher Tagungsreisen, die große Freiheit bei der Arbeit, die zu der sehr produktiven Arbeitsatmosphäre innerhalb seiner Gruppe führt, seine hilfreiche Beratung bei Bewerbungen, die finanzielle Unterstützung und nicht zuletzt für die Zusammenstellung und Führung einer trotz ihrer Größe so harmonischen und menschlich angenehmen Arbeitsgruppe ganz herzlich bedanken.

Herrn PD Dr. *KLAUS REUTER* danke ich herzlich für die Betreuung meiner Arbeit, die vielen Gespräche bei Problemen, seine stete Hilfsbereitschaft, sowie die große Gastfreundschaft, die ich als „Untermieter“ in seinem Büro erfahren habe.

Dr. *ANDREAS HEINE* danke ich für die Einführung in die kristallographischen Methoden, seine immer interessierte Bereitschaft schwierige Kristallstrukturen zu begutachten und die sehr netten Synchrotron-Reisen, bei denen ich viel von ihm gelernt habe.

Prof. Dr. *CHRISTOPH SOTRIFFER* danke ich ganz besonders für die Einführung in das Aufsetzen und Analysieren von MD Simulationen, die Diskussionen und das Korrekturlesen vieler Posterentwürfe. Während der Betreuung des Erstsemesterpraktikums habe ich seine immer sehr geduldige, höfliche, äußerst kompetente und stets interessierte Art mit Menschen umzugehen sehr zu schätzen gelernt. Für die Planung der vielen schönen Wanderungen in Hirschegg und die damit verbundenen Erinnerungen möchte ich mich ebenfalls ganz herzlich bedanken.

Dr. *BERNHARD STENGL* danke ich ganz besonders für die äußerst produktive und nette Kooperation nicht nur bezüglich der E235Q-Mutagenesestudie.

Allen Mitgliedern und Ehemaligen der Arbeitsgruppe danke ich für die nette Arbeitsatmosphäre und den guten Gruppenzusammenhalt. Den Computer-Administratoren Dr. *NILS WESKAMP* und Dr. *MATTHIAS ZENTGRAF* danke ich für ihre ständige Bereitschaft zur schnellen und freundlichen Hilfe. *GERD NEUDERT* und *SVEN SIEBLER* danke ich für die Einführung in die Programmiersprache Python.

Bei *JOHANNES SCHULZE WISCHELER* und *CHRISTIAN HASEWINKEL* möchte ich mich für die nette Zusammenarbeit während ihrer Diplomarbeiten bedanken.

*ANDREAS RATJE* danke ich für die Etablierung und freundliche Übergabe des MALDI-TOF/MS assays.

Dr. *SILKE SEEGER* und *NICO VOGEL* (Universität Erlangen-Nürnberg) danke ich für die Durchführung zahlreicher MALDI-TOF/MS Analysen. *CLAUDIA SASS* danke ich für die „Magnetic beads“-Aufreinigung der Proben.

*HANS-DIETER GERBER* danke ich für die Synthesen von Queuin, preQ<sub>1</sub> und -Derivaten.

Bei *ANJA VOGT* möchte ich mich für die unkomplizierte und freundliche Zusammenarbeit bzgl. der LC/MS Analyse von Queuin-Proben bedanken.

Ich danke allen meinen Praktikanten, insbesondere *LARA-MARIA DREWES*, *JOHANNES SCHULZE WISCHELER*, *NINA ZIMMER*, *NADJA HERKERT* und *DORIS DOBRIN*, für die Unterstützung bei der Klonierung und Expression von *Shigella* Invasinen.

Bei *STEFFI DÖRR* bedanke ich mich für ihre tatkräftige Hilfe bei der TGT-Aufreinigung.

PD Dr. *THOMAS ADAM* (Charité Berlin) danke ich für Bereitstellung und Präparation des *Shigella* Virulenzplasmids pCP301.

*JÖRG KAHNT* (MPI Marburg) danke ich für die MALDI-TOF/MS Analyse von IpgE.

Dem DFG Graduiertenkolleg „Proteinfunktion auf atomarer Ebene“ danke ich für die finanzielle Unterstützung.

*MEINER FAMILIE*, insbesondere *MEINEN ELTERN* möchte ich für ihre immerwährende Unterstützung, ihr stetes Interesse und den seelisch-moralischen Beistand in allen Lebenslagen meinen zutiefst empfundenen Dank aussprechen.

Ganz besonders danken möchte ich *INKEN PAYSSEN*, *TINA HUNGER* und *ALWIN SCHÄFER* für die enge Freundschaft, die stets aufmunternde Worte, viel Verständnis und geduldiges Anhören von Problemen.

*SIMONE*, *GERO* und *ROMAN SCHERMUTZKI* möchte ich für die außerordentliche menschliche Bereicherung neben der Promotion ganz herzlich danken. Meinem Patenkind *ROMAN* dabei zusehen zu dürfen, wie er die Welt um sich herum entdeckt, empfinde ich als ein ganz großes Geschenk.

Dr. *PAUL CZODROWSKI*, Dr. *ANDREAS BLUM*, *JARK BÖTTCHER*, Dr. *VIDA ZOHRABI*, Dr. *MATTHIAS ZENTGRAF*, Dr. *KATRIN SILBER*, *JOHANNES SCHULZE WISCHELER*, *LISA ENGLERT* und *BERNHARD BAUM* möchte ich ganz besonders für die vielen netten Stunden, Gespräche und die schöne Zeit in Marburg während und neben der Promotion danken.

*TORSTEN LUKSCH* verdanke ich eine ausgelassen schöne und erfüllte Zeit in Marburg, in der er durch sein einfühlsames Verständnis und seine Geduld, seine tiefe Freundschaft und Verbundenheit und nicht zuletzt durch seine Liebe mich und mein Leben unendlich bereichert hat.

## Erklärung

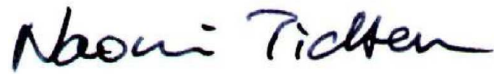

Ich versichere, dass ich meine Dissertation

### **Structural and mutational characterisation of *Shigella* Pathogenicity Factors**

selbständig, ohne unerlaubte Hilfe angefertigt und mich dabei keiner anderen als der von mir ausdrücklich bezeichneten Quellen bedient habe.

Die Dissertation wurde in der jetzigen oder einer ähnlichen Form noch bei keiner anderen Hochschule eingereicht und hat noch keinen sonstigen Prüfungszwecken gedient.

Marburg, den 12.12.2007

(Naomi Tidten)

## Curriculum Vitae

**Naomi Tidten** (Dipl.–Biochem.)

Date of Birth: Dec, 8<sup>th</sup> 1978 in Bonn, Germany.

### School Education

1985 – 1992 Deutsche Schule Tokyo, Japan (Accredited German School Abroad).

06/1998 High School Diploma, Gymnasium Icking, Germany.

### University Studies

1998 – 2003 Study of biochemistry (Universität Bayreuth, Germany).

08/2002 – 02/2003 Diploma thesis, Topic: “*Cloning and characterisation of miniGC-C, an extracellular domain fragment of the Guanylyl-cyclase-C*” (Lehrstuhl für Struktur und Chemie der Biopolymere, research group of Prof. Dr. P. Rösch, Universität Bayreuth, Germany).

### Internships

07/1998 – 09/1998 Bayerische Landesanstalt für Bodenkultur und Pflanzenbau – Bavarian Institute of Crop and Plant Cultivation, Freising, Germany.

09/1998 – 10/1998 Prof. Dr. Robert Huber, Max Planck Institut für Biochemie, Martinsried, Germany.

02/2004 – 05/2004 Aventis Pharma, Department of Structural Biology, Frankfurt/Main, Germany.

<b>Scientific Work</b>
------------------------

- 05/2003 – 09/2003 Research stay (Kwansei Gakuin University, Sanda, Prof. Dr. H. Yamaguchi, and Osaka University, Prof. Dr. Y. Hidaka, Japan), supported by a German Academic Exchange Service (DAAD) grant.
- 10/2003 – 01/2004 Research stay (Lehrstuhl für Struktur und Chemie der Biopolymere, research group of PD Dr. U. C. Marx, Universität Bayreuth, Germany) supported by a grant of the Universität Bayreuth (Gesetz zur Förderung des wissenschaftlichen und künstlerischen Nachwuchses in Bayern – BayNwFG).
- since 05/2004 PhD project: “*Structural and mutational characterisation of Shigella Pathogenicity Factors*” (Institut für Pharmazeutische Chemie, research group of Prof. Dr. G. Klebe/ PD Dr. K. Reuter, Philipps-Universität Marburg, Germany), supported by a DFG Graduiertenkolleg grant “Protein function at the atomic level”.

<b>Publications</b>
---------------------

Schulz A., Marx U. C., Tidten N., Lauber T., Hidaka Y., Adermann K.:

*Side chain contributions to the interconversion of the topological isomers of guanylin-like peptides*, J Pept. Sci. **2005 Jun**; 11(6): 319–30.

Tidten N., Stengl B., Heine A., Garcia G. A., Klebe G., Reuter K.:

*Glutamate versus Glutamine exchange waps substrate selectivity in tRNA-guanine transglycosylase: Isight into the regulation of substrate selectivity by kinetic and crystallographic studies*, J Mol. Biol. **2007 Nov**; 374(3): 764–76.

<b>Oral Presentations</b>
---------------------------

- 09/2005 Anglo-German-Japanese Biochemistry Meeting, Kyoto, Japan: *Substrate specificities of eukaryotic and eubacterial tRNA-guanine transglycosylases*.
- 09/2006 Graduiertenkolleg 541 „*Proteinfunktion auf atomarer Ebene*“ Symposium, Marburg, Germany: *Mutational study on substrate specificity of tRNA-guanine transglycosylases*.

<b>Poster Presentations</b>
-----------------------------

- 01/2005 First FECS school on protein chemistry, Brixen, Italy:  
*Unravelling substrate specificity & flexibility in binding pockets of the TGT system*  
(Tidten N., Stengl B., Meyer E., Heine A., Brenk R., Diederich F., Reuter K.).
- 03/2005 56. Mosbacher Kolloquium der Gesellschaft für Biochemie und Molekularbiologie, Mosbach (Baden), Germany:  
*Studies of Peptide Hormone/Receptor Interactions by NMR Spectroscopy*  
(Vitzithum K., Link N., Schuster D., Tidten N., Lauber T., Rösch P., Marx U.C.).
- 03/2006 Gesellschaft Deutscher Chemiker (GDCh) Annual Meeting "Frontiers in Medicinal Chemistry", Frankfurt/Main, Germany:  
*Mutational studies on substrate specificity in tRNA guanine trans-glycosylase binding pockets*  
(Tidten N., Sotriffer C., Gerber H.-D., Stengl B., Reuter K., Klebe G.).
- 05/2006 8th International School on the Crystallography of Biological Macromolecules, Como, Italy:  
*Flexibility & specificity of TGT elucidated by MD and crystal structure analysis*  
(Tidten N., Sotriffer C., Gerber H.-D., Stengl B., Reuter K., Klebe G.).
- 08/2006 1st European Chemistry Congress, Budapest, Hungary:  
*Unravelling substrate specificity & flexibility in binding pockets of the TGT system*  
(Tidten, N., Sotriffer, C., Gerber, H.-D., Stengl, B., Reuter, K., Klebe, G.).
- 03/2007 Gesellschaft Deutscher Chemiker (GDCh) Annual Meeting "Frontiers in Medicinal Chemistry", Berlin, Germany:  
*Glu vs. Gln exchange swaps substrate specificity in TGT – Insight into the regulation of substrate selectivity*  
(Tidten N., Stengl B., Heine A., Klebe G., Reuter K.).
